NAME

subpage_prot − define a subpage protection for an address range

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/syscall.h>      /* Definition of SYS_* constants */
#include <unistd.h>

int syscall(SYS_subpage_prot, unsigned long addr, unsigned long len,
        uint32_t *map);
```

Note: glibc provides no wrapper for **subpage_prot**(), necessitating the use of *syscall*(2).

DESCRIPTION

The PowerPC-specific **subpage_prot**() system call provides the facility to control the access permissions on individual 4 kB subpages on systems configured with a page size of 64 kB.

The protection map is applied to the memory pages in the region starting at *addr* and continuing for *len* bytes. Both of these arguments must be aligned to a 64-kB boundary.

The protection map is specified in the buffer pointed to by *map*. The map has 2 bits per 4 kB subpage; thus each 32-bit word specifies the protections of 16 4 kB subpages inside a 64 kB page (so, the number of 32-bit words pointed to by *map* should equate to the number of 64-kB pages specified by *len*). Each 2-bit field in the protection map is either 0 to allow any access, 1 to prevent writes, or 2 or 3 to prevent all accesses.

RETURN VALUE

On success, **subpage_prot**() returns 0. Otherwise, one of the error codes specified below is returned.

ERRORS

EFAULT
: The buffer referred to by *map* is not accessible.

EINVAL
: The *addr* or *len* arguments are incorrect. Both of these arguments must be aligned to a multiple of the system page size, and they must not refer to a region outside of the address space of the process or to a region that consists of huge pages.

ENOMEM
: Out of memory.

STANDARDS

Linux.

HISTORY

Linux 2.6.25 (PowerPC).

The system call is provided only if the kernel is configured with **CONFIG_PPC_64K_PAGES**.

NOTES

Normal page protections (at the 64-kB page level) also apply; the subpage protection mechanism is an additional constraint, so putting 0 in a 2-bit field won't allow writes to a page that is otherwise write-protected.

Rationale

This system call is provided to assist writing emulators that operate using 64-kB pages on PowerPC systems. When emulating systems such as x86, which uses a smaller page size, the emulator can no longer use the memory-management unit (MMU) and normal system calls for controlling page protections. (The emulator could emulate the MMU by checking and possibly remapping the address for each memory access in software, but that is slow.) The idea is that the emulator supplies an array of protection masks to apply to a specified range of virtual addresses. These masks are applied at the level where hardware page-table entries (PTEs) are inserted into the hardware page table based on the Linux PTEs, so the Linux PTEs are not affected. Implicit in this is that the regions of the address space that are protected are switched to use 4-kB hardware pages rather than 64-kB hardware pages (on machines with hardware 64-kB page support).

NAME

swapon, swapoff − start/stop swapping to file/device

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/swap.h>

int swapon(const char *path, int swapflags);
int swapoff(const char *path);
```

DESCRIPTION

swapon() sets the swap area to the file or block device specified by *path*. **swapoff**() stops swapping to the file or block device specified by *path*.

If the **SWAP_FLAG_PREFER** flag is specified in the **swapon**() *swapflags* argument, the new swap area will have a higher priority than default. The priority is encoded within *swapflags* as:

```
(prio << SWAP_FLAG_PRIO_SHIFT) & SWAP_FLAG_PRIO_MASK
```

If the **SWAP_FLAG_DISCARD** flag is specified in the **swapon**() *swapflags* argument, freed swap pages will be discarded before they are reused, if the swap device supports the discard or trim operation. (This may improve performance on some Solid State Devices, but often it does not.) See also NOTES.

These functions may be used only by a privileged process (one having the **CAP_SYS_ADMIN** capability).

Priority

Each swap area has a priority, either high or low. The default priority is low. Within the low-priority areas, newer areas are even lower priority than older areas.

All priorities set with *swapflags* are high-priority, higher than default. They may have any nonnegative value chosen by the caller. Higher numbers mean higher priority.

Swap pages are allocated from areas in priority order, highest priority first. For areas with different priorities, a higher-priority area is exhausted before using a lower-priority area. If two or more areas have the same priority, and it is the highest priority available, pages are allocated on a round-robin basis between them.

As of Linux 1.3.6, the kernel usually follows these rules, but there are exceptions.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EBUSY
(for *swapon*()) The specified *path* is already being used as a swap area.

EINVAL
The file *path* exists, but refers neither to a regular file nor to a block device;

EINVAL
(**swapon**()) The indicated path does not contain a valid swap signature or resides on an in-memory filesystem such as *tmpfs*(5).

EINVAL (since Linux 3.4)
(**swapon**()) An invalid flag value was specified in *swapflags*.

EINVAL
(**swapoff**()) *path* is not currently a swap area.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOENT
The file *path* does not exist.

ENOMEM
The system has insufficient memory to start swapping.

EPERM
The caller does not have the **CAP_SYS_ADMIN** capability. Alternatively, the maximum number of swap files are already in use; see NOTES below.

STANDARDS
Linux.

HISTORY
The *swapflags* argument was introduced in Linux 1.3.2.

NOTES
The partition or path must be prepared with *mkswap*(8)

There is an upper limit on the number of swap files that may be used, defined by the kernel constant **MAX_SWAPFILES**. Before Linux 2.4.10, **MAX_SWAPFILES** has the value 8; since Linux 2.4.10, it has the value 32. Since Linux 2.6.18, the limit is decreased by 2 (thus 30), since Linux 5.19, the limit is decreased by 3 (thus: 29) if the kernel is built with the **CONFIG_MIGRATION** option (which reserves two swap table entries for the page migration features of *mbind*(2) and *migrate_pages*(2)). Since Linux 2.6.32, the limit is further decreased by 1 if the kernel is built with the **CONFIG_MEMORY_FAILURE** option. Since Linux 5.14, the limit is further decreased by 4 if the kernel is built with the **CONFIG_DEVICE_PRIVATE** option. Since Linux 5.19, the limit is further decreased by 1 if the kernel is built with the **CONFIG_PTE_MARKER** option.

Discard of swap pages was introduced in Linux 2.6.29, then made conditional on the **SWAP_FLAG_DISCARD** flag in Linux 2.6.36, which still discards the entire swap area when **swapon**() is called, even if that flag bit is not set.

NAME

symlink, symlinkat − make a new name for a file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

int symlink(const char *target, const char *linkpath);

#include <fcntl.h>           /* Definition of AT_* constants */
#include <unistd.h>

int symlinkat(const char *target, int newdirfd, const char *linkpath);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

symlink():
_XOPEN_SOURCE >= 500 || _POSIX_C_SOURCE >= 200112L
|| /* glibc <= 2.19: */ _BSD_SOURCE

symlinkat():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_ATFILE_SOURCE

DESCRIPTION

symlink() creates a symbolic link named *linkpath* which contains the string *target*.

Symbolic links are interpreted at run time as if the contents of the link had been substituted into the path being followed to find a file or directory.

Symbolic links may contain .. path components, which (if used at the start of the link) refer to the parent directories of that in which the link resides.

A symbolic link (also known as a soft link) may point to an existing file or to a nonexistent one; the latter case is known as a dangling link.

The permissions of a symbolic link are irrelevant; the ownership is ignored when following the link (except when the *protected_symlinks* feature is enabled, as explained in *proc*(5)), but is checked when removal or renaming of the link is requested and the link is in a directory with the sticky bit (**S_ISVTX**) set.

If *linkpath* exists, it will *not* be overwritten.

symlinkat()

The **symlinkat**() system call operates in exactly the same way as **symlink**(), except for the differences described here.

If the pathname given in *linkpath* is relative, then it is interpreted relative to the directory referred to by the file descriptor *newdirfd* (rather than relative to the current working directory of the calling process, as is done by **symlink**() for a relative pathname).

If *linkpath* is relative and *newdirfd* is the special value **AT_FDCWD**, then *linkpath* is interpreted relative to the current working directory of the calling process (like *symlink*())

If *linkpath* is absolute, then *newdirfd* is ignored.

See *openat*(2) for an explanation of the need for **symlinkat**().

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EACCES
Write access to the directory containing *linkpath* is denied, or one of the directories in the path prefix of *linkpath* did not allow search permission. (See also *path_resolution*(7).)

EBADF
(**symlinkat**()) *linkpath* is relative but *newdirfd* is neither **AT_FDCWD** nor a valid file descriptor.

EDQUOT
The user's quota of resources on the filesystem has been exhausted. The resources could be inodes or disk blocks, depending on the filesystem implementation.

EEXIST
linkpath already exists.

EFAULT
target or *linkpath* points outside your accessible address space.

EIO An I/O error occurred.

ELOOP
Too many symbolic links were encountered in resolving *linkpath*.

ENAMETOOLONG
target or *linkpath* was too long.

ENOENT
A directory component in *linkpath* does not exist or is a dangling symbolic link, or *target* or *linkpath* is an empty string.

ENOENT
(**symlinkat**()) *linkpath* is a relative pathname and *newdirfd* refers to a directory that has been deleted.

ENOMEM
Insufficient kernel memory was available.

ENOSPC
The device containing the file has no room for the new directory entry.

ENOTDIR
A component used as a directory in *linkpath* is not, in fact, a directory.

ENOTDIR
(**symlinkat**()) *linkpath* is relative and *newdirfd* is a file descriptor referring to a file other than a directory.

EPERM
The filesystem containing *linkpath* does not support the creation of symbolic links.

EROFS
linkpath is on a read-only filesystem.

STANDARDS
POSIX.1-2008.

HISTORY
symlink()
SVr4, 4.3BSD, POSIX.1-2001.

symlinkat()
POSIX.1-2008. Linux 2.6.16, glibc 2.4.

glibc notes
On older kernels where **symlinkat**() is unavailable, the glibc wrapper function falls back to the use of **symlink**(). When *linkpath* is a relative pathname, glibc constructs a pathname based on the symbolic link in */proc/self/fd* that corresponds to the *newdirfd* argument.

NOTES
No checking of *target* is done.

Deleting the name referred to by a symbolic link will actually delete the file (unless it also has other hard links). If this behavior is not desired, use *link*(2).

NAME

sync, syncfs − commit filesystem caches to disk

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

void sync(void);

int syncfs(int fd);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sync():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE

syncfs():
_GNU_SOURCE

DESCRIPTION

sync() causes all pending modifications to filesystem metadata and cached file data to be written to the underlying filesystems.

syncfs() is like **sync**(), but synchronizes just the filesystem containing file referred to by the open file descriptor *fd*.

RETURN VALUE

syncfs() returns 0 on success; on error, it returns −1 and sets *errno* to indicate the error.

ERRORS

sync() is always successful.

syncfs() can fail for at least the following reasons:

EBADF
fd is not a valid file descriptor.

EIO An error occurred during synchronization. This error may relate to data written to any file on the filesystem, or on metadata related to the filesystem itself.

ENOSPC
Disk space was exhausted while synchronizing.

ENOSPC
EDQUOT
Data was written to a file on NFS or another filesystem which does not allocate space at the time of a *write*(2) system call, and some previous write failed due to insufficient storage space.

VERSIONS

According to the standard specification (e.g., POSIX.1-2001), **sync**() schedules the writes, but may return before the actual writing is done. However Linux waits for I/O completions, and thus **sync**() or **syncfs**() provide the same guarantees as **fsync**() called on every file in the system or filesystem respectively.

STANDARDS

sync() POSIX.1-2008.

syncfs()
Linux.

HISTORY

sync() POSIX.1-2001, SVr4, 4.3BSD.

syncfs()
Linux 2.6.39, glibc 2.14.

Since glibc 2.2.2, the Linux prototype for **sync**() is as listed above, following the various standards. In glibc 2.2.1 and earlier, it was "int sync(void)", and **sync**() always returned 0.

In mainline kernel versions prior to Linux 5.8, **syncfs**() will fail only when passed a bad file descriptor (**EBADF**). Since Linux 5.8, **syncfs**() will also report an error if one or more inodes failed to be written back since the last **syncfs**() call.

BUGS

Before Linux 1.3.20, Linux did not wait for I/O to complete before returning.

SEE ALSO

sync(1), *fdatasync*(2), *fsync*(2)

NAME

sync_file_range − sync a file segment with disk

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#define _FILE_OFFSET_BITS 64
#include <fcntl.h>

int sync_file_range(int fd, off_t offset, off_t nbytes,
                    unsigned int flags);
```

DESCRIPTION

sync_file_range() permits fine control when synchronizing the open file referred to by the file descriptor *fd* with disk.

offset is the starting byte of the file range to be synchronized. *nbytes* specifies the length of the range to be synchronized, in bytes; if *nbytes* is zero, then all bytes from *offset* through to the end of file are synchronized. Synchronization is in units of the system page size: *offset* is rounded down to a page boundary; *(offset+nbytes−1)* is rounded up to a page boundary.

The *flags* bit-mask argument can include any of the following values:

SYNC_FILE_RANGE_WAIT_BEFORE
: Wait upon write-out of all pages in the specified range that have already been submitted to the device driver for write-out before performing any write.

SYNC_FILE_RANGE_WRITE
: Initiate write-out of all dirty pages in the specified range which are not presently submitted write-out. Note that even this may block if you attempt to write more than request queue size.

SYNC_FILE_RANGE_WAIT_AFTER
: Wait upon write-out of all pages in the range after performing any write.

Specifying *flags* as 0 is permitted, as a no-op.

Warning

This system call is extremely dangerous and should not be used in portable programs. None of these operations writes out the file's metadata. Therefore, unless the application is strictly performing overwrites of already-instantiated disk blocks, there are no guarantees that the data will be available after a crash. There is no user interface to know if a write is purely an overwrite. On filesystems using copy-on-write semantics (e.g., *btrfs*) an overwrite of existing allocated blocks is impossible. When writing into preallocated space, many filesystems also require calls into the block allocator, which this system call does not sync out to disk. This system call does not flush disk write caches and thus does not provide any data integrity on systems with volatile disk write caches.

Some details

SYNC_FILE_RANGE_WAIT_BEFORE and **SYNC_FILE_RANGE_WAIT_AFTER** will detect any I/O errors or **ENOSPC** conditions and will return these to the caller.

Useful combinations of the *flags* bits are:

SYNC_FILE_RANGE_WAIT_BEFORE | SYNC_FILE_RANGE_WRITE
: Ensures that all pages in the specified range which were dirty when **sync_file_range**() was called are placed under write-out. This is a start-write-for-data-integrity operation.

SYNC_FILE_RANGE_WRITE
: Start write-out of all dirty pages in the specified range which are not presently under write-out. This is an asynchronous flush-to-disk operation. This is not suitable for data integrity operations.

SYNC_FILE_RANGE_WAIT_BEFORE (or **SYNC_FILE_RANGE_WAIT_AFTER**)
: Wait for completion of write-out of all pages in the specified range. This can be used after an earlier **SYNC_FILE_RANGE_WAIT_BEFORE | SYNC_FILE_RANGE_WRITE** operation to wait for completion of that operation, and obtain its result.

SYNC_FILE_RANGE_WAIT_BEFORE | SYNC_FILE_RANGE_WRITE | SYNC_FILE_RANGE_WAIT_AFTER
This is a write-for-data-integrity operation that will ensure that all pages in the specified range which were dirty when **sync_file_range**() was called are committed to disk.

RETURN VALUE

On success, **sync_file_range**() returns 0; on failure −1 is returned and *errno* is set to indicate the error.

ERRORS

EBADF
fd is not a valid file descriptor.

EINVAL
flags specifies an invalid bit; or *offset* or *nbytes* is invalid.

EIO I/O error.

ENOMEM
Out of memory.

ENOSPC
Out of disk space.

ESPIPE
fd refers to something other than a regular file, a block device, or a directory.

VERSIONS

sync_file_range2()
Some architectures (e.g., PowerPC, ARM) need 64-bit arguments to be aligned in a suitable pair of registers. On such architectures, the call signature of **sync_file_range**() shown in the SYNOPSIS would force a register to be wasted as padding between the *fd* and *offset* arguments. (See *syscall*(2) for details.) Therefore, these architectures define a different system call that orders the arguments suitably:

```
int sync_file_range2(int fd, unsigned int flags,
                     off_t offset, off_t nbytes);
```

The behavior of this system call is otherwise exactly the same as **sync_file_range**().

STANDARDS

Linux.

HISTORY

Linux 2.6.17.

sync_file_range2()
A system call with this signature first appeared on the ARM architecture in Linux 2.6.20, with the name **arm_sync_file_range**(). It was renamed in Linux 2.6.22, when the analogous system call was added for PowerPC. On architectures where glibc support is provided, glibc transparently wraps **sync_file_range2**() under the name **sync_file_range**().

NOTES

_FILE_OFFSET_BITS should be defined to be 64 in code that takes the address of **sync_file_range**, if the code is intended to be portable to traditional 32-bit x86 and ARM platforms where **off_t**'s width defaults to 32 bits.

SEE ALSO

fdatasync(2), *fsync*(2), *msync*(2), *sync*(2)

NAME

syscall − indirect system call

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/syscall.h> /* Definition of **SYS_*** constants */
#include <unistd.h>

long syscall(long *number***, ...);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

syscall():
Since glibc 2.19:
_DEFAULT_SOURCE
Before glibc 2.19:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

syscall() is a small library function that invokes the system call whose assembly language interface has the specified *number* with the specified arguments. Employing **syscall**() is useful, for example, when invoking a system call that has no wrapper function in the C library.

syscall() saves CPU registers before making the system call, restores the registers upon return from the system call, and stores any error returned by the system call in *errno*(3).

Symbolic constants for system call numbers can be found in the header file <*sys/syscall.h*>.

RETURN VALUE

The return value is defined by the system call being invoked. In general, a 0 return value indicates success. A −1 return value indicates an error, and an error number is stored in *errno*.

ERRORS

ENOSYS
The requested system call number is not implemented.

Other errors are specific to the invoked system call.

NOTES

syscall() first appeared in 4BSD.

Architecture-specific requirements

Each architecture ABI has its own requirements on how system call arguments are passed to the kernel. For system calls that have a glibc wrapper (e.g., most system calls), glibc handles the details of copying arguments to the right registers in a manner suitable for the architecture. However, when using **syscall**() to make a system call, the caller might need to handle architecture-dependent details; this requirement is most commonly encountered on certain 32-bit architectures.

For example, on the ARM architecture Embedded ABI (EABI), a 64-bit value (e.g., *long long*) must be aligned to an even register pair. Thus, using **syscall**() instead of the wrapper provided by glibc, the *readahead*(2) system call would be invoked as follows on the ARM architecture with the EABI in little endian mode:

```
syscall(SYS_readahead, fd, 0,
        (unsigned int) (offset & 0xFFFFFFFF),
        (unsigned int) (offset >> 32),
        count);
```

Since the offset argument is 64 bits, and the first argument (*fd*) is passed in *r0*, the caller must manually split and align the 64-bit value so that it is passed in the *r2*/*r3* register pair. That means inserting a dummy value into *r1* (the second argument of 0). Care also must be taken so that the split follows endian conventions (according to the C ABI for the platform).

Similar issues can occur on MIPS with the O32 ABI, on PowerPC and parisc with the 32-bit ABI, and on Xtensa.

Note that while the parisc C ABI also uses aligned register pairs, it uses a shim layer to hide the issue

from user space.

The affected system calls are *fadvise64_64*(2), *ftruncate64*(2), *posix_fadvise*(2), *pread64*(2), *pwrite64*(2), *readahead*(2), *sync_file_range*(2), and *truncate64*(2).

This does not affect syscalls that manually split and assemble 64-bit values such as *_llseek*(2), *preadv*(2), *preadv2*(2), *pwritev*(2), and *pwritev2*(2). Welcome to the wonderful world of historical baggage.

Architecture calling conventions

Every architecture has its own way of invoking and passing arguments to the kernel. The details for various architectures are listed in the two tables below.

The first table lists the instruction used to transition to kernel mode (which might not be the fastest or best way to transition to the kernel, so you might have to refer to *vdso*(7)), the register used to indicate the system call number, the register(s) used to return the system call result, and the register used to signal an error.

Notes:

- On a few architectures, a register is used as a boolean (0 indicating no error, and −1 indicating an error) to signal that the system call failed. The actual error value is still contained in the return register. On sparc, the carry bit (*csr*) in the processor status register (*psr*) is used instead of a full register. On powerpc64, the summary overflow bit (*SO*) in field 0 of the condition register (*cr0*) is used.
- *NR* is the system call number.
- For s390 and s390x, *NR* (the system call number) may be passed directly with *svc NR* if it is less than 256.
- On SuperH additional trap numbers are supported for historic reasons, but **trapa**#31 is the recommended "unified" ABI.

- The x32 ABI shares syscall table with x86-64 ABI, but there are some nuances:
  - In order to indicate that a system call is called under the x32 ABI, an additional bit, **__X32_SYSCALL_BIT**, is bitwise ORed with the system call number. The ABI used by a process affects some process behaviors, including signal handling or system call restarting.
  - Since x32 has different sizes for *long* and pointer types, layouts of some (but not all; *struct timeval* or *struct rlimit* are 64-bit, for example) structures are different. In order to handle this, additional system calls are added to the system call table, starting from number 512 (without the **__X32_SYSCALL_BIT**). For example, **__NR_readv** is defined as 19 for the x86-64 ABI and as *__X32_SYSCALL_BIT* | **515** for the x32 ABI. Most of these additional system calls are actually identical to the system calls used for providing i386 compat. There are some notable exceptions, however, such as *preadv2*(2), which uses *struct iovec* entities with 4-byte pointers and sizes ("compat_iovec" in kernel terms), but passes an 8-byte *pos* argument in a single register and not two, as is done in every other ABI.
- Some architectures (namely, Alpha, IA-64, MIPS, SuperH, sparc/32, and sparc/64) use an additional register ("Retval2" in the above table) to pass back a second return value from the *pipe*(2) system call; Alpha uses this technique in the architecture-specific *getxpid*(2), *getxuid*(2), and *getxgid*(2) system calls as well. Other architectures do not use the second return value register in the system call interface, even if it is defined in the System V ABI.

The second table shows the registers used to pass the system call arguments.

Notes:

- The mips/o32 system call convention passes arguments 5 through 8 on the user stack.

Note that these tables don’t cover the entire calling convention—some architectures may indiscriminately clobber other registers not listed here.

EXAMPLES

```
#define _GNU_SOURCE
#include <signal.h>
#include <sys/syscall.h>
#include <unistd.h>

int
main(void)
{
    pid_t tid;

    tid = syscall(SYS_gettid);
    syscall(SYS_tgkill, getpid(), tid, SIGHUP);
}
```

SEE ALSO

NAME

_syscall − invoking a system call without library support (OBSOLETE)

SYNOPSIS

#include <linux/unistd.h>

A _syscall macro

desired system call

DESCRIPTION

The important thing to know about a system call is its prototype. You need to know how many arguments, their types, and the function return type. There are seven macros that make the actual call into the system easier. They have the form:

```
_syscallX(type,name,type1,arg1,type2,arg2,...)
```

where

X is 0–6, which are the number of arguments taken by the system call

type is the return type of the system call

name is the name of the system call

typeN is the Nth argument's type

argN is the name of the Nth argument

These macros create a function called *name* with the arguments you specify. Once you include the _syscall() in your source file, you call the system call by *name*.

FILES

/usr/include/linux/unistd.h

STANDARDS

Linux.

HISTORY

Starting around Linux 2.6.18, the _syscall macros were removed from header files supplied to user space. Use *syscall*(2) instead. (Some architectures, notably ia64, never provided the _syscall macros; on those architectures, *syscall*(2) was always required.)

NOTES

The _syscall() macros *do not* produce a prototype. You may have to create one, especially for C++ users.

System calls are not required to return only positive or negative error codes. You need to read the source to be sure how it will return errors. Usually, it is the negative of a standard error code, for example, −*EPERM*. The _syscall() macros will return the result *r* of the system call when *r* is nonnegative, but will return −1 and set the variable *errno* to −*r* when *r* is negative. For the error codes, see *errno*(3).

When defining a system call, the argument types *must* be passed by-value or by-pointer (for aggregates like structs).

EXAMPLES

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <linux/unistd.h>       /* for _syscallX macros/related stuff */
#include <linux/kernel.h>       /* for struct sysinfo */

_syscall1(int, sysinfo, struct sysinfo *, info);

int
main(void)
{
    struct sysinfo s_info;
    int error;
```

```
        error = sysinfo(&s_info);
        printf("code error = %d\n", error);
        printf("Uptime = %lds\nLoad: 1 min %lu / 5 min %lu / 15 min %lu\n"
               "RAM: total %lu / free %lu / shared %lu\n"
               "Memory in buffers = %lu\nSwap: total %lu / free %lu\n"
               "Number of processes = %d\n",
               s_info.uptime, s_info.loads[0],
               s_info.loads[1], s_info.loads[2],
               s_info.totalram, s_info.freeram,
               s_info.sharedram, s_info.bufferram,
               s_info.totalswap, s_info.freeswap,
               s_info.procs);
        exit(EXIT_SUCCESS);
    }
```

Sample output

```
    code error = 0
    uptime = 502034s
    Load: 1 min 13376 / 5 min 5504 / 15 min 1152
    RAM: total 15343616 / free 827392 / shared 8237056
    Memory in buffers = 5066752
    Swap: total 27881472 / free 24698880
    Number of processes = 40
```

NAME

syscalls − Linux system calls

SYNOPSIS

Linux system calls.

DESCRIPTION

The system call is the fundamental interface between an application and the Linux kernel.

System calls and library wrapper functions

System calls are generally not invoked directly, but rather via wrapper functions in glibc (or perhaps some other library). For details of direct invocation of a system call, see *intro*(2). Often, but not always, the name of the wrapper function is the same as the name of the system call that it invokes. For example, glibc contains a function **chdir**() which invokes the underlying "chdir" system call.

Often the glibc wrapper function is quite thin, doing little work other than copying arguments to the right registers before invoking the system call, and then setting *errno* appropriately after the system call has returned. (These are the same steps that are performed by *syscall*(2), which can be used to invoke system calls for which no wrapper function is provided.) Note: system calls indicate a failure by returning a negative error number to the caller on architectures without a separate error register/flag, as noted in *syscall*(2); when this happens, the wrapper function negates the returned error number (to make it positive), copies it to *errno*, and returns −1 to the caller of the wrapper.

Sometimes, however, the wrapper function does some extra work before invoking the system call. For example, nowadays there are (for reasons described below) two related system calls, *truncate*(2) and *truncate64*(2), and the glibc **truncate**() wrapper function checks which of those system calls are provided by the kernel and determines which should be employed.

System call list

Below is a list of the Linux system calls. In the list, the *Kernel* column indicates the kernel version for those system calls that were new in Linux 2.2, or have appeared since that kernel version. Note the following points:

- Where no kernel version is indicated, the system call appeared in Linux 1.0 or earlier.
- Where a system call is marked "1.2" this means the system call probably appeared in a Linux 1.1.x kernel version, and first appeared in a stable kernel with 1.2. (Development of the Linux 1.2 kernel was initiated from a branch of Linux 1.0.6 via the Linux 1.1.x unstable kernel series.)
- Where a system call is marked "2.0" this means the system call probably appeared in a Linux 1.3.x kernel version, and first appeared in a stable kernel with Linux 2.0. (Development of the Linux 2.0 kernel was initiated from a branch of Linux 1.2.x, somewhere around Linux 1.2.10, via the Linux 1.3.x unstable kernel series.)
- Where a system call is marked "2.2" this means the system call probably appeared in a Linux 2.1.x kernel version, and first appeared in a stable kernel with Linux 2.2.0. (Development of the Linux 2.2 kernel was initiated from a branch of Linux 2.0.21 via the Linux 2.1.x unstable kernel series.)
- Where a system call is marked "2.4" this means the system call probably appeared in a Linux 2.3.x kernel version, and first appeared in a stable kernel with Linux 2.4.0. (Development of the Linux 2.4 kernel was initiated from a branch of Linux 2.2.8 via the Linux 2.3.x unstable kernel series.)
- Where a system call is marked "2.6" this means the system call probably appeared in a Linux 2.5.x kernel version, and first appeared in a stable kernel with Linux 2.6.0. (Development of Linux 2.6 was initiated from a branch of Linux 2.4.15 via the Linux 2.5.x unstable kernel series.)
- Starting with Linux 2.6.0, the development model changed, and new system calls may appear in each Linux 2.6.x release. In this case, the exact version number where the system call appeared is shown. This convention continues with the Linux 3.x kernel series, which followed on from Linux 2.6.39; and the Linux 4.x kernel series, which followed on from Linux 3.19; and the Linux 5.x kernel series, which followed on from Linux 4.20; and the Linux 6.x kernel series, which followed on from Linux 5.19.
- In some cases, a system call was added to a stable kernel series after it branched from the previous stable kernel series, and then backported into the earlier stable kernel series. For example some system calls that appeared in Linux 2.6.x were also backported into a Linux 2.4.x release after Linux 2.4.15. When this is so, the version where the system call appeared in both of the major

kernel series is listed.

The list of system calls that are available as at Linux 5.14 (or in a few cases only on older kernels) is as follows:

System call	Kernel	Notes
_llseek(2)	1.2	
_newselect(2)	2.0	
_sysctl(2)	2.0	Removed in 5.5
accept(2)	2.0	See notes on *socketcall*(2)
accept4(2)	2.6.28	
access(2)	1.0	
acct(2)	1.0	
add_key(2)	2.6.10	
adjtimex(2)	1.0	
alarm(2)	1.0	
alloc_hugepages(2)	2.5.36	Removed in 2.5.44
arc_gettls(2)	3.9	ARC only
arc_settls(2)	3.9	ARC only
arc_usr_cmpxchg(2)	4.9	ARC only
arch_prctl(2)	2.6	x86_64, x86 since 4.12
atomic_barrier(2)	2.6.34	m68k only
atomic_cmpxchg_32(2)	2.6.34	m68k only
bdflush(2)	1.2	Deprecated (does nothing) since 2.6
bind(2)	2.0	See notes on *socketcall*(2)
bpf(2)	3.18	
brk(2)	1.0	
breakpoint(2)	2.2	ARM OABI only, defined with **__ARM_NR** prefix
cacheflush(2)	1.2	Not on x86
capget(2)	2.2	
capset(2)	2.2	
chdir(2)	1.0	
chmod(2)	1.0	
chown(2)	2.2	See *chown*(2) for version details
chown32(2)	2.4	
chroot(2)	1.0	
clock_adjtime(2)	2.6.39	
clock_getres(2)	2.6	
clock_gettime(2)	2.6	
clock_nanosleep(2)	2.6	
clock_settime(2)	2.6	
clone2(2)	2.4	IA-64 only
clone(2)	1.0	
clone3(2)	5.3	
close(2)	1.0	
close_range(2)	5.9	
connect(2)	2.0	See notes on *socketcall*(2)
copy_file_range(2)	4.5	
creat(2)	1.0	
create_module(2)	1.0	Removed in 2.6
delete_module(2)	1.0	
dup(2)	1.0	
dup2(2)	1.0	
dup3(2)	2.6.27	
epoll_create(2)	2.6	
epoll_create1(2)	2.6.27	

epoll_ctl(2)	2.6	
epoll_pwait(2)	2.6.19	
epoll_pwait2(2)	5.11	
epoll_wait(2)	2.6	
eventfd(2)	2.6.22	
eventfd2(2)	2.6.27	
execv(2)	2.0	SPARC/SPARC64 only, for compatibility with SunOS
execve(2)	1.0	
execveat(2)	3.19	
exit(2)	1.0	
exit_group(2)	2.6	
faccessat(2)	2.6.16	
faccessat2(2)	5.8	
fadvise64(2)	2.6	
fadvise64_64(2)	2.6	
fallocate(2)	2.6.23	
fanotify_init(2)	2.6.37	
fanotify_mark(2)	2.6.37	
fchdir(2)	1.0	
fchmod(2)	1.0	
fchmodat(2)	2.6.16	
fchown(2)	1.0	
fchown32(2)	2.4	
fchownat(2)	2.6.16	
fcntl(2)	1.0	
fcntl64(2)	2.4	
fdatasync(2)	2.0	
fgetxattr(2)	2.6; 2.4.18	
finit_module(2)	3.8	
flistxattr(2)	2.6; 2.4.18	
flock(2)	2.0	
fork(2)	1.0	
free_hugepages(2)	2.5.36	Removed in 2.5.44
fremovexattr(2)	2.6; 2.4.18	
fsconfig(2)	5.2	
fsetxattr(2)	2.6; 2.4.18	
fsmount(2)	5.2	
fsopen(2)	5.2	
fspick(2)	5.2	
fstat(2)	1.0	
fstat64(2)	2.4	
fstatat64(2)	2.6.16	
fstatfs(2)	1.0	
fstatfs64(2)	2.6	
fsync(2)	1.0	
ftruncate(2)	1.0	
ftruncate64(2)	2.4	
futex(2)	2.6	
futimesat(2)	2.6.16	
get_kernel_syms(2)	1.0	Removed in 2.6
get_mempolicy(2)	2.6.6	
get_robust_list(2)	2.6.17	
get_thread_area(2)	2.6	
get_tls(2)	4.15	ARM OABI only, has **__ARM_NR** prefix
getcpu(2)	2.6.19	
getcwd(2)	2.2	

getdents(2)	2.0	
getdents64(2)	2.4	
getdomainname(2)	2.2	SPARC, SPARC64; available as*osf_getdomainname*(2) on Alpha since Linux 2.0
getdtablesize(2)	2.0	SPARC (removed in 2.6.26), available on Alpha as *osf_getdtablesize*(2)
getegid(2)	1.0	
getegid32(2)	2.4	
geteuid(2)	1.0	
geteuid32(2)	2.4	
getgid(2)	1.0	
getgid32(2)	2.4	
getgroups(2)	1.0	
getgroups32(2)	2.4	
gethostname(2)	2.0	Alpha, was available on SPARC up to Linux 2.6.26
getitimer(2)	1.0	
getpeername(2)	2.0	See notes on *socketcall*(2)
getpagesize(2)	2.0	Not on x86
getpgid(2)	1.0	
getpgrp(2)	1.0	
getpid(2)	1.0	
getppid(2)	1.0	
getpriority(2)	1.0	
getrandom(2)	3.17	
getresgid(2)	2.2	
getresgid32(2)	2.4	
getresuid(2)	2.2	
getresuid32(2)	2.4	
getrlimit(2)	1.0

nanosleep(2)	2.0	
newfstatat(2)	2.6.16	See *stat*(2)
nfsservctl(2)	2.2	Removed in 3.1
nice(2)	1.0	
old_adjtimex(2)	2.0	Alpha only; see NOTES
old_getrlimit(2)	2.4	Old variant of *getrlimit*(2) that used a different value for **RLIM_INFINITY**
oldfstat(2)	1.0	
oldlstat(2)	1.0	
oldolduname(2)	1.0	
oldstat(2)	1.0	
oldumount(2)	2.4.116	Name of the old *umount*(2) syscall on Alpha
olduname(2)	1.0	
open(2)	1.0	
open_by_handle_at(2)	2.6.39	
open_tree(2)	5.2	
openat(2)	2.6.16	
openat2(2)	5.6	
or1k_atomic(2)	3.1	OpenRISC 1000 only
pause(2)	1.0	
pciconfig_iobase(2)	2.2.15; 2.4	Not on x86
pciconfig_read(2)	2.0.26; 2.2	Not on x86
pciconfig_write(2)	2.0.26; 2.2	Not on x86
perf_event_open(2)	2.6.31	Was perf_counter_open() in 2.6.31; renamed in 2.6.32
personality(2)	1.2	
perfctr(2)	2.2	SPARC only; removed in 2.6.34
perfmonctl(2)	2.4	IA-64 only; removed in 5.10
pidfd_getfd(2)	5.6	
pidfd_send_signal(2)	5.1	
pidfd_open(2)	5.3	
pipe(2)	1.0	
pipe2(2)	2.6.27	
pivot_root(2)	2.4	
pkey_alloc(2)	4.8	
pkey_free(2)	4.8	
pkey_mprotect(2)	4.8	
poll(2)	2.0.36; 2.2	
ppoll(2)	2.6.16	
prctl(2)	2.2	
pread64(2)		Added as "pread" in 2.2; renamed "pread64" in 2.6
preadv(2)	2.6.30	

preadv2(2)	4.6	
prlimit64(2)	2.6.36	
process_madvise(2)	5.10	
process_vm_readv(2)	3.2	
process_vm_writev(2)	3.2	
pselect6(2)	2.6.16	
ptrace(2)	1.0	
pwrite64(2)		Added as "pwrite" in 2.2; renamed "pwrite64" in 2.6
pwritev(2)	2.6.30	
pwritev2(2)	4.6	
query_module(2)	2.2	Removed in 2.6
quotactl(2)	1.0	
quotactl_fd(2)	5.14	
read(2)	1.0	
readahead(2)	2.4.13	
readdir(2)	1.0	
readlink(2)	1.0	
readlinkat(2)	2.6.16	
readv(2)	2.0	
reboot(2)	1.0	
recv(2)	2.0	See notes on *socketcall*(2)
recvfrom(2)	2.0	See notes on *socketcall*(2)
recvmsg(2)	2.0	See notes on *socketcall*(2)
recvmmsg(2)	2.6.33	
remap_file_pages(2)	2.6	Deprecated since 3.16
removexattr(2)	2.6; 2.4.18	
rename(2)	1.0	
renameat(2)	2.6.16	
renameat2(2)	3.15	
request_key(2)	2.6.10	
restart_syscall(2)	2.6

On many platforms, including x86-32, socket calls are all multiplexed (via glibc wrapper functions) through *socketcall*(2) and similarly System V IPC calls are multiplexed through *ipc*(2).

Although slots are reserved for them in the system call table, the following system calls are not implemented in the standard kernel: *afs_syscall*(2), *break*(2), *ftime*(2), *getpmsg*(2), *gtty*(2), *idle*(2), *lock*(2), *madvise1*(2), *mpx*(2), *phys*(2), *prof*(2), *profil*(2), *putpmsg*(2), *security*(2), *stty*(2), *tuxcall*(2), *ulimit*(2), and *vserver*(2) (see also *unimplemented*(2)). However, *ftime*(3), *profil*(3), and *ulimit*(3) exist as library routines. The slot for *phys*(2) is in use since Linux 2.1.116 for *umount*(2); *phys*(2) will never be implemented. The *getpmsg*(2) and *putpmsg*(2) calls are for kernels patched to support STREAMS, and may never be in the standard kernel.

There was briefly *set_zone_reclaim*(2), added in Linux 2.6.13, and removed in Linux 2.6.16; this system call was never available to user space.

System calls on removed ports

Some system calls only ever existed on Linux architectures that have since been removed from the kernel:

AVR32 (port removed in Linux 4.12)

- *pread*(2)
- *pwrite*(2)

Blackfin (port removed in Linux 4.17)

- *bfin_spinlock*(2) (added in Linux 2.6.22)
- *dma_memcpy*(2) (added in Linux 2.6.22)
- *pread*(2) (added in Linux 2.6.22)
- *pwrite*(2) (added in Linux 2.6.22)
- *sram_alloc*(2) (added in Linux 2.6.22)
- *sram_free*(2) (added in Linux 2.6.22)

Metag (port removed in Linux 4.17)

- *metag_get_tls*(2) (add in Linux 3.9)
- *metag_set_fpu_flags*(2) (add in Linux 3.9)
- *metag_set_tls*(2) (add in Linux 3.9)
- *metag_setglobalbit*(2) (add in Linux 3.9)

Tile (port removed in Linux 4.17)

- *cmpxchg_badaddr*(2) (added in Linux 2.6.36)

NOTES

Roughly speaking, the code belonging to the system call with number __NR_xxx defined in */usr/include/asm/unistd.h* can be found in the Linux kernel source in the routine *sys_xxx*(). There are many exceptions, however, mostly because older system calls were superseded by newer ones, and this has been treated somewhat unsystematically. On platforms with proprietary operating-system emulation, such as sparc, sparc64, and alpha, there are many additional system calls; mips64 also contains a full set of 32-bit system calls.

Over time, changes to the interfaces of some system calls have been necessary. One reason for such changes was the need to increase the size of structures or scalar values passed to the system call. Because of these changes, certain architectures (notably, longstanding 32-bit architectures such as i386) now have various groups of related system calls (e.g., *truncate*(2) and *truncate64*(2)) which perform similar tasks, but which vary in details such as the size of their arguments. (As noted earlier, applications are generally unaware of this: the glibc wrapper functions do some work to ensure that the right system call is invoked, and that ABI compatibility is preserved for old binaries.) Examples of system calls that exist in multiple versions are the following:

- By now there are three different versions of *stat*(2): *sys_stat*() (slot *__NR_oldstat*), *sys_newstat*() (slot *__NR_stat*), and *sys_stat64*() (slot *__NR_stat64*), with the last being the most current. A similar story applies for *lstat*(2) and *fstat*(2).
- Similarly, the defines *__NR_oldolduname*, *__NR_olduname*, and *__NR_uname* refer to the routines *sys_olduname*(), *sys_uname*(), and *sys_newuname*().
- In Linux 2.0, a new version of *vm86*(2) appeared, with the old and the new kernel routines being named *sys_vm86old*() and *sys_vm86*().
- In Linux 2.4, a new version of *getrlimit*(2) appeared, with the old and the new kernel routines being named *sys_old_getrlimit*() (slot *__NR_getrlimit*) and *sys_getrlimit*() (slot *__NR_ugetrlimit*).
- Linux 2.4 increased the size of user and group IDs from 16 to 32 bits. To support this change, a range of system calls were added (e.g., *chown32*(2), *getuid32*(2), *getgroups32*(2), *setresuid32*(2)), superseding earlier calls of the same name without the "32" suffix.
- Linux 2.4 added support for applications on 32-bit architectures to access large files (i.e., files for which the sizes and file offsets can't be represented in 32 bits.) To support this change, replacements were required for system calls that deal with file offsets and sizes. Thus the following system calls were added: *fcntl64*(2), *getdents64*(2), *stat64*(2), *statfs64*(2), *truncate64*(2), and their analogs that work with file descriptors or symbolic links. These system calls supersede the older system calls which, except in the case of the "stat" calls, have the same name without the "64" suffix.

  On newer platforms that only have 64-bit file access and 32-bit UIDs/GIDs (e.g., alpha, ia64, s390x, x86-64), there is just a single version of the UID/GID and file access system calls. On platforms (typically, 32-bit platforms) where the *64 and *32 calls exist, the other versions are obsolete.

- The *rt_sig** calls were added in Linux 2.2 to support the addition of real-time signals (see *signal*(7)). These system calls supersede the older system calls of the same name without the "rt_" prefix.
- The *select*(2) and *mmap*(2) system calls use five or more arguments, which caused problems in the way argument passing on the i386 used to be set up. Thus, while other architectures have *sys_select*() and *sys_mmap*() corresponding to *__NR_select* and *__NR_mmap*, on i386 one finds *old_select*() and *old_mmap*() (routines that use a pointer to an argument block) instead. These days passing five arguments is not a problem any more, and there is a *__NR__newselect* that corresponds directly to *sys_select*() and similarly *__NR_mmap2*. s390x is the only 64-bit architecture that has *old_mmap*().

Architecture-specific details: Alpha

getxgid(2)
: returns a pair of GID and effective GID via registers **r0** and **r20**; it is provided instead of **getgid**(2) and **getegid**(2).

getxpid(2)
: returns a pair of PID and parent PID via registers **r0** and **r20**; it is provided instead of **getpid**(2) and **getppid**(2).

old_adjtimex(2)
: is a variant of **adjtimex**(2) that uses *struct timeval32*, for compatibility with OSF/1.

getxuid(2)
: returns a pair of GID and effective GID via registers **r0** and **r20**; it is provided instead of **getuid**(2) and **geteuid**(2).

sethae(2)
: is used for configuring the Host Address Extension register on low-cost Alphas in order to access address space beyond first 27 bits.

NAME

sysctl − read/write system parameters

SYNOPSIS

#include <unistd.h>
#include <linux/sysctl.h>

[[deprecated]] int _sysctl(struct __sysctl_args **args*);

DESCRIPTION

This system call no longer exists on current kernels! See NOTES.

The **_sysctl**() call reads and/or writes kernel parameters. For example, the hostname, or the maximum number of open files. The argument has the form

```
struct __sysctl_args {
    int    *name;    /* integer vector describing variable */
    int     nlen;    /* length of this vector */
    void   *oldval;  /* 0 or address where to store old value */
    size_t *oldlenp; /* available room for old value,
                        overwritten by actual size of old value */
    void   *newval;  /* 0 or address of new value */
    size_t  newlen;  /* size of new value */
};
```

This call does a search in a tree structure, possibly resembling a directory tree under */proc/sys*, and if the requested item is found calls some appropriate routine to read or modify the value.

RETURN VALUE

Upon successful completion, **_sysctl**() returns 0. Otherwise, a value of −1 is returned and *errno* is set to indicate the error.

ERRORS

EACCES
EPERM
No search permission for one of the encountered "directories", or no read permission where *oldval* was nonzero, or no write permission where *newval* was nonzero.

EFAULT
The invocation asked for the previous value by setting *oldval* non-NULL, but allowed zero room in *oldlenp*.

ENOTDIR
name was not found.

STANDARDS

Linux.

HISTORY

Linux 1.3.57. Removed in Linux 5.5, glibc 2.32.

It originated in 4.4BSD. Only Linux has the */proc/sys* mirror, and the object naming schemes differ between Linux and 4.4BSD, but the declaration of the **sysctl**() function is the same in both.

NOTES

Use of this system call was long discouraged: since Linux 2.6.24, uses of this system call result in warnings in the kernel log, and in Linux 5.5, the system call was finally removed. Use the */proc/sys* interface instead.

Note that on older kernels where this system call still exists, it is available only if the kernel was configured with the **CONFIG_SYSCTL_SYSCALL** option. Furthermore, glibc does not provide a wrapper for this system call, necessitating the use of *syscall*(2).

BUGS

The object names vary between kernel versions, making this system call worthless for applications.

Not all available objects are properly documented.

It is not yet possible to change operating system by writing to */proc/sys/kernel/ostype*.

EXAMPLES

```
#define _GNU_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/syscall.h>
#include <unistd.h>

#include <linux/sysctl.h>

#define ARRAY_SIZE(arr)  (sizeof(arr) / sizeof((arr)[0]))

int _sysctl(struct __sysctl_args *args);

#define OSNAMESZ 100

int
main(void)
{
    int                  name[] = { CTL_KERN, KERN_OSTYPE };
    char                 osname[OSNAMESZ];
    size_t               osnamelth;
    struct __sysctl_args  args;

    memset(&args, 0, sizeof(args));
    args.name = name;
    args.nlen = ARRAY_SIZE(name);
    args.oldval = osname;
    args.oldlenp = &osnamelth;

    osnamelth = sizeof(osname);

    if (syscall(SYS__sysctl, &args) == -1) {
        perror("_sysctl");
        exit(EXIT_FAILURE);
    }
    printf("This machine is running %*s\n", (int) osnamelth, osname);
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

proc(5)

NAME

sysfs − get filesystem type information

SYNOPSIS

[[deprecated]] int sysfs(int *option***, const char *** *fsname***);**
[[deprecated]] int sysfs(int *option***, unsigned int** *fs_index***, char *** *buf* **);**
[[deprecated]] int sysfs(int *option***);**

DESCRIPTION

Note: if you are looking for information about the **sysfs** filesystem that is normally mounted at */sys*, see *sysfs*(5).

The (obsolete) **sysfs**() system call returns information about the filesystem types currently present in the kernel. The specific form of the **sysfs**() call and the information returned depends on the *option* in effect:

1 Translate the filesystem identifier string *fsname* into a filesystem type index.

2 Translate the filesystem type index *fs_index* into a null-terminated filesystem identifier string. This string will be written to the buffer pointed to by *buf* . Make sure that *buf* has enough space to accept the string.

3 Return the total number of filesystem types currently present in the kernel.

The numbering of the filesystem type indexes begins with zero.

RETURN VALUE

On success, **sysfs**() returns the filesystem index for option **1**, zero for option **2**, and the number of currently configured filesystems for option **3**. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT
Either *fsname* or *buf* is outside your accessible address space.

EINVAL
fsname is not a valid filesystem type identifier; *fs_index* is out-of-bounds; *option* is invalid.

STANDARDS

None.

HISTORY

SVr4.

This System-V derived system call is obsolete; don't use it. On systems with */proc*, the same information can be obtained via */proc*; use that interface instead.

BUGS

There is no libc or glibc support. There is no way to guess how large *buf* should be.

SEE ALSO

proc(5), *sysfs*(5)

NAME

sysinfo − return system information

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/sysinfo.h>

int sysinfo(struct sysinfo *****info*);**

DESCRIPTION

sysinfo() returns certain statistics on memory and swap usage, as well as the load average.

Until Linux 2.3.16, **sysinfo**() returned information in the following structure:

```
struct sysinfo {
    long uptime;             /* Seconds since boot */
    unsigned long loads[3];  /* 1, 5, and 15 minute load averages */
    unsigned long totalram;  /* Total usable main memory size */
    unsigned long freeram;   /* Available memory size */
    unsigned long sharedram; /* Amount of shared memory */
    unsigned long bufferram; /* Memory used by buffers */
    unsigned long totalswap; /* Total swap space size */
    unsigned long freeswap;  /* Swap space still available */
    unsigned short procs;    /* Number of current processes */
    char _f[22];             /* Pads structure to 64 bytes */
};
```

In the above structure, the sizes of the memory and swap fields are given in bytes.

Since Linux 2.3.23 (i386) and Linux 2.3.48 (all architectures) the structure is:

```
struct sysinfo {
    long uptime;             /* Seconds since boot */
    unsigned long loads[3];  /* 1, 5, and 15 minute load averages */
    unsigned long totalram;  /* Total usable main memory size */
    unsigned long freeram;   /* Available memory size */
    unsigned long sharedram; /* Amount of shared memory */
    unsigned long bufferram; /* Memory used by buffers */
    unsigned long totalswap; /* Total swap space size */
    unsigned long freeswap;  /* Swap space still available */
    unsigned short procs;    /* Number of current processes */
    unsigned long totalhigh; /* Total high memory size */
    unsigned long freehigh;  /* Available high memory size */
    unsigned int mem_unit;   /* Memory unit size in bytes */
    char _f[20-2*sizeof(long)-sizeof(int)];
                             /* Padding to 64 bytes */
};
```

In the above structure, sizes of the memory and swap fields are given as multiples of *mem_unit* bytes.

RETURN VALUE

On success, **sysinfo**() returns zero. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT

info is not a valid address.

STANDARDS

Linux.

HISTORY

Linux 0.98.pl6.

NOTES

All of the information provided by this system call is also available via */proc/meminfo* and */proc/loadavg*.

SEE ALSO

proc(5)

NAME

syslog, klogctl − read and/or clear kernel message ring buffer; set console_loglevel

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/klog.h>      /* Definition of SYSLOG_* constants */
#include <sys/syscall.h>   /* Definition of SYS_* constants */
#include <unistd.h>

int syscall(SYS_syslog, int type, char *bufp, int len);

/* The glibc interface */
#include <sys/klog.h>

int klogctl(int type, char *bufp, int len);
```

DESCRIPTION

Note: Probably, you are looking for the C library function **syslog**(), which talks to *syslogd*(8); see *syslog*(3) for details.

This page describes the kernel **syslog**() system call, which is used to control the kernel *printk*() buffer; the glibc wrapper function for the system call is called **klogctl**().

The kernel log buffer

The kernel has a cyclic buffer of length **LOG_BUF_LEN** in which messages given as arguments to the kernel function **printk**() are stored (regardless of their log level). In early kernels, **LOG_BUF_LEN** had the value 4096; from Linux 1.3.54, it was 8192; from Linux 2.1.113, it was 16384; since Linux 2.4.23/2.6, the value is a kernel configuration option (**CONFIG_LOG_BUF_SHIFT**, default value dependent on the architecture). Since Linux 2.6.6, the size can be queried with command type 10 (see below).

Commands

The *type* argument determines the action taken by this function. The list below specifies the values for *type*. The symbolic names are defined in the kernel source, but are not exported to user space; you will either need to use the numbers, or define the names yourself.

SYSLOG_ACTION_CLOSE (0)
: Close the log. Currently a NOP.

SYSLOG_ACTION_OPEN (1)
: Open the log. Currently a NOP.

SYSLOG_ACTION_READ (2)
: Read from the log. The call waits until the kernel log buffer is nonempty, and then reads at most *len* bytes into the buffer pointed to by *bufp*. The call returns the number of bytes read. Bytes read from the log disappear from the log buffer: the information can be read only once. This is the function executed by the kernel when a user program reads */proc/kmsg*.

SYSLOG_ACTION_READ_ALL (3)
: Read all messages remaining in the ring buffer, placing them in the buffer pointed to by *bufp*. The call reads the last *len* bytes from the log buffer (nondestructively), but will not read more than was written into the buffer since the last "clear ring buffer" command (see command 5 below)). The call returns the number of bytes read.

SYSLOG_ACTION_READ_CLEAR (4)
: Read and clear all messages remaining in the ring buffer. The call does precisely the same as for a *type* of 3, but also executes the "clear ring buffer" command.

SYSLOG_ACTION_CLEAR (5)
: The call executes just the "clear ring buffer" command. The *bufp* and *len* arguments are ignored.

  This command does not really clear the ring buffer. Rather, it sets a kernel bookkeeping variable that determines the results returned by commands 3 (**SYSLOG_ACTION_READ_ALL**) and 4 (**SYSLOG_ACTION_READ_CLEAR**). This command has no effect on commands 2 (**SYSLOG_ACTION_READ**) and 9 (**SYSLOG_ACTION_SIZE_UNREAD**).

SYSLOG_ACTION_CONSOLE_OFF (6)
The command saves the current value of *console_loglevel* and then sets *console_loglevel* to *minimum_console_loglevel*, so that no messages are printed to the console. Before Linux 2.6.32, the command simply sets *console_loglevel* to *minimum_console_loglevel*. See the discussion of */proc/sys/kernel/printk*, below.

The *bufp* and *len* arguments are ignored.

SYSLOG_ACTION_CONSOLE_ON (7)
If a previous **SYSLOG_ACTION_CONSOLE_OFF** command has been performed, this command restores *console_loglevel* to the value that was saved by that command. Before Linux 2.6.32, this command simply sets *console_loglevel* to *default_console_loglevel*. See the discussion of */proc/sys/kernel/printk*, below.

The *bufp* and *len* arguments are ignored.

SYSLOG_ACTION_CONSOLE_LEVEL (8)
The call sets *console_loglevel* to the value given in *len*, which must be an integer between 1 and 8 (inclusive). The kernel silently enforces a minimum value of *minimum_console_loglevel* for *len*. See the *log level* section for details. The *bufp* argument is ignored.

SYSLOG_ACTION_SIZE_UNREAD (9) (since Linux 2.4.10)
The call returns the number of bytes currently available to be read from the kernel log buffer via command 2 (**SYSLOG_ACTION_READ**). The *bufp* and *len* arguments are ignored.

SYSLOG_ACTION_SIZE_BUFFER (10) (since Linux 2.6.6)
This command returns the total size of the kernel log buffer. The *bufp* and *len* arguments are ignored.

All commands except 3 and 10 require privilege. In Linux kernels before Linux 2.6.37, command types 3 and 10 are allowed to unprivileged processes; since Linux 2.6.37, these commands are allowed to unprivileged processes only if */proc/sys/kernel/dmesg_restrict* has the value 0. Before Linux 2.6.37, "privileged" means that the caller has the **CAP_SYS_ADMIN** capability. Since Linux 2.6.37, "privileged" means that the caller has either the **CAP_SYS_ADMIN** capability (now deprecated for this purpose) or the (new) **CAP_SYSLOG** capability.

/proc/sys/kernel/printk
/proc/sys/kernel/printk is a writable file containing four integer values that influence kernel *printk()* behavior when printing or logging error messages. The four values are:

console_loglevel
Only messages with a log level lower than this value will be printed to the console. The default value for this field is **DEFAULT_CONSOLE_LOGLEVEL** (7), but it is set to 4 if the kernel command line contains the word "quiet", 10 if the kernel command line contains the word "debug", and to 15 in case of a kernel fault (the 10 and 15 are just silly, and equivalent to 8). The value of *console_loglevel* can be set (to a value in the range 1–8) by a **syslog**() call with a *type* of 8.

default_message_loglevel
This value will be used as the log level for *printk()* messages that do not have an explicit level. Up to and including Linux 2.6.38, the hard-coded default value for this field was 4 (**KERN_WARNING**); since Linux 2.6.39, the default value is defined by the kernel configuration option **CONFIG_DEFAULT_MESSAGE_LOGLEVEL**, which defaults to 4.

minimum_console_loglevel
The value in this field is the minimum value to which *console_loglevel* can be set.

default_console_loglevel
This is the default value for *console_loglevel*.

The log level
Every *printk*() message has its own log level. If the log level is not explicitly specified as part of the message, it defaults to *default_message_loglevel*. The conventional meaning of the log level is as follows:

Kernel constant **Level value** **Meaning**

KERN_EMERG	0	System is unusable
KERN_ALERT	1	Action must be taken immediately
KERN_CRIT	2	Critical conditions
KERN_ERR	3	Error conditions
KERN_WARNING	4	Warning conditions
KERN_NOTICE	5	Normal but significant condition
KERN_INFO	6	Informational
KERN_DEBUG	7	Debug-level messages

The kernel *printk()* routine will print a message on the console only if it has a log level less than the value of *console_loglevel*.

RETURN VALUE

For *type* equal to 2, 3, or 4, a successful call to **syslog**() returns the number of bytes read. For *type* 9, **syslog**() returns the number of bytes currently available to be read on the kernel log buffer. For *type* 10, **syslog**() returns the total size of the kernel log buffer. For other values of *type*, 0 is returned on success.

In case of error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL
: Bad arguments (e.g., bad *type*; or for *type* 2, 3, or 4, *buf* is NULL, or *len* is less than zero; or for *type* 8, the *level* is outside the range 1 to 8).

ENOSYS
: This **syslog**() system call is not available, because the kernel was compiled with the **CONFIG_PRINTK** kernel-configuration option disabled.

EPERM
: An attempt was made to change *console_loglevel* or clear the kernel message ring buffer by a process without sufficient privilege (more precisely: without the **CAP_SYS_ADMIN** or **CAP_SYSLOG** capability).

ERESTARTSYS
: System call was interrupted by a signal; nothing was read. (This can be seen only during a trace.)

STANDARDS

Linux.

HISTORY

From the very start, people noted that it is unfortunate that a system call and a library routine of the same name are entirely different animals.

dmesg(1), *syslog*(3), *capabilities*(7)

NAME

tee − duplicating pipe content

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <fcntl.h>

ssize_t tee(int fd_in, int fd_out, size_t len, unsigned int flags);
```

DESCRIPTION

tee() duplicates up to *len* bytes of data from the pipe referred to by the file descriptor *fd_in* to the pipe referred to by the file descriptor *fd_out*. It does not consume the data that is duplicated from *fd_in*; therefore, that data can be copied by a subsequent *splice*(2).

flags is a bit mask that is composed by ORing together zero or more of the following values:

SPLICE_F_MOVE Currently has no effect for **tee**(); see *splice*(2).

SPLICE_F_NONBLOCK Do not block on I/O; see *splice*(2) for further details.

SPLICE_F_MORE Currently has no effect for **tee**(), but may be implemented in the future; see *splice*(2).

SPLICE_F_GIFT Unused for **tee**(); see *vmsplice*(2).

RETURN VALUE

Upon successful completion, **tee**() returns the number of bytes that were duplicated between the input and output. A return value of 0 means that there was no data to transfer, and it would not make sense to block, because there are no writers connected to the write end of the pipe referred to by *fd_in*.

On error, **tee**() returns −1 and *errno* is set to indicate the error.

ERRORS

EAGAIN
: **SPLICE_F_NONBLOCK** was specified in *flags* or one of the file descriptors had been marked as nonblocking (**O_NONBLOCK**), and the operation would block.

EINVAL
: *fd_in* or *fd_out* does not refer to a pipe; or *fd_in* and *fd_out* refer to the same pipe.

ENOMEM
: Out of memory.

STANDARDS

Linux.

HISTORY

Linux 2.6.17, glibc 2.5.

NOTES

Conceptually, **tee**() copies the data between the two pipes. In reality no real data copying takes place though: under the covers, **tee**() assigns data to the output by merely grabbing a reference to the input.

EXAMPLES

The example below implements a basic *tee*(1) program using the **tee**() system call. Here is an example of its use:

```
$ date | ./a.out out.log | cat
Tue Oct 28 10:06:00 CET 2014
$ cat out.log
Tue Oct 28 10:06:00 CET 2014
```

Program source

```
#define _GNU_SOURCE
#include <errno.h>
#include <fcntl.h>
#include <limits.h>
```

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    int      fd;
    ssize_t  len, slen;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s <file>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    fd = open(argv[1], O_WRONLY | O_CREAT | O_TRUNC, 0644);
    if (fd == -1) {
        perror("open");
        exit(EXIT_FAILURE);
    }

    for (;;) {
        /*
         * tee stdin to stdout.
         */
        len = tee(STDIN_FILENO, STDOUT_FILENO,
                  INT_MAX, SPLICE_F_NONBLOCK);
        if (len < 0) {
            if (errno == EAGAIN)
                continue;
            perror("tee");
            exit(EXIT_FAILURE);
        }
        if (len == 0)
            break;

        /*
         * Consume stdin by splicing it to a file.
         */
        while (len > 0) {
            slen = splice(STDIN_FILENO, NULL, fd, NULL,
                          len, SPLICE_F_MOVE);
            if (slen < 0) {
                perror("splice");
                exit(EXIT_FAILURE);
            }
            len -= slen;
        }
    }

    close(fd);
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

splice(2), *vmsplice*(2), *pipe*(7)

NAME

time − get time in seconds

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <time.h>

time_t time(time_t *_Nullable tloc);
```

DESCRIPTION

time() returns the time as the number of seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC).

If *tloc* is non-NULL, the return value is also stored in the memory pointed to by *tloc*.

RETURN VALUE

On success, the value of time in seconds since the Epoch is returned. On error, *((time_t) −1)* is returned, and *errno* is set to indicate the error.

ERRORS

EOVERFLOW

The time cannot be represented as a *time_t* value. This can happen if an executable with 32-bit *time_t* is run on a 64-bit kernel when the time is 2038-01-19 03:14:08 UTC or later. However, when the system time is out of *time_t* range in other situations, the behavior is undefined.

EFAULT

tloc points outside your accessible address space (but see BUGS).

On systems where the C library **time**() wrapper function invokes an implementation provided by the *vdso*(7) (so that there is no trap into the kernel), an invalid address may instead trigger a **SIGSEGV** signal.

VERSIONS

POSIX.1 defines *seconds since the Epoch* using a formula that approximates the number of seconds between a specified time and the Epoch. This formula takes account of the facts that all years that are evenly divisible by 4 are leap years, but years that are evenly divisible by 100 are not leap years unless they are also evenly divisible by 400, in which case they are leap years. This value is not the same as the actual number of seconds between the time and the Epoch, because of leap seconds and because system clocks are not required to be synchronized to a standard reference. Linux systems normally follow the POSIX requirement that this value ignore leap seconds, so that conforming systems interpret it consistently; see POSIX.1-2018 Rationale A.4.16.

Applications intended to run after 2038 should use ABIs with *time_t* wider than 32 bits; see *time_t*(3type).

C library/kernel differences

On some architectures, an implementation of **time**() is provided in the *vdso*(7).

STANDARDS

C11, POSIX.1-2008.

HISTORY

SVr4, 4.3BSD, C89, POSIX.1-2001.

BUGS

Error returns from this system call are indistinguishable from successful reports that the time is a few seconds *before* the Epoch, so the C library wrapper function never sets *errno* as a result of this call.

The *tloc* argument is obsolescent and should always be NULL in new code. When *tloc* is NULL, the call cannot fail.

NAME

timer_create − create a POSIX per-process timer

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <signal.h>          /* Definition of SIGEV_* constants */
#include <time.h>

int timer_create(clockid_t clockid,
                 struct sigevent *_Nullable restrict sevp,
                 timer_t *restrict timerid);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

timer_create():
_POSIX_C_SOURCE >= 199309L

DESCRIPTION

timer_create() creates a new per-process interval timer. The ID of the new timer is returned in the buffer pointed to by *timerid*, which must be a non-null pointer. This ID is unique within the process, until the timer is deleted. The new timer is initially disarmed.

The *clockid* argument specifies the clock that the new timer uses to measure time. It can be specified as one of the following values:

CLOCK_REALTIME
A settable system-wide real-time clock.

CLOCK_MONOTONIC
A nonsettable monotonically increasing clock that measures time from some unspecified point in the past that does not change after system startup.

CLOCK_PROCESS_CPUTIME_ID (since Linux 2.6.12)
A clock that measures (user and system) CPU time consumed by (all of the threads in) the calling process.

CLOCK_THREAD_CPUTIME_ID (since Linux 2.6.12)
A clock that measures (user and system) CPU time consumed by the calling thread.

CLOCK_BOOTTIME (Since Linux 2.6.39)
Like **CLOCK_MONOTONIC**, this is a monotonically increasing clock. However, whereas the **CLOCK_MONOTONIC** clock does not measure the time while a system is suspended, the **CLOCK_BOOTTIME** clock does include the time during which the system is suspended. This is useful for applications that need to be suspend-aware. **CLOCK_REALTIME** is not suitable for such applications, since that clock is affected by discontinuous changes to the system clock.

CLOCK_REALTIME_ALARM (since Linux 3.0)
This clock is like **CLOCK_REALTIME**, but will wake the system if it is suspended. The caller must have the **CAP_WAKE_ALARM** capability in order to set a timer against this clock.

CLOCK_BOOTTIME_ALARM (since Linux 3.0)
This clock is like **CLOCK_BOOTTIME**, but will wake the system if it is suspended. The caller must have the **CAP_WAKE_ALARM** capability in order to set a timer against this clock.

CLOCK_TAI (since Linux 3.10)
A system-wide clock derived from wall-clock time but counting leap seconds.

See *clock_getres*(2) for some further details on the above clocks.

As well as the above values, *clockid* can be specified as the *clockid* returned by a call to *clock_getcpuclockid*(3) or *pthread_getcpuclockid*(3).

The *sevp* argument points to a *sigevent* structure that specifies how the caller should be notified when the timer expires. For the definition and general details of this structure, see *sigevent*(3type).

The *sevp.sigev_notify* field can have the following values:

SIGEV_NONE
Don't asynchronously notify when the timer expires. Progress of the timer can be monitored using *timer_gettime*(2).

SIGEV_SIGNAL
Upon timer expiration, generate the signal *sigev_signo* for the process. See *sigevent*(3type) for general details. The *si_code* field of the *siginfo_t* structure will be set to **SI_TIMER**. At any point in time, at most one signal is queued to the process for a given timer; see *timer_getoverrun*(2) for more details.

SIGEV_THREAD
Upon timer expiration, invoke *sigev_notify_function* as if it were the start function of a new thread. See *sigevent*(3type) for details.

SIGEV_THREAD_ID (Linux-specific)
As for **SIGEV_SIGNAL**, but the signal is targeted at the thread whose ID is given in *sigev_notify_thread_id*, which must be a thread in the same process as the caller. The *sigev_notify_thread_id* field specifies a kernel thread ID, that is, the value returned by *clone*(2) or *gettid*(2). This flag is intended only for use by threading libraries.

Specifying *sevp* as NULL is equivalent to specifying a pointer to a *sigevent* structure in which *sigev_notify* is **SIGEV_SIGNAL**, *sigev_signo* is **SIGALRM**, and *sigev_value.sival_int* is the timer ID.

RETURN VALUE

On success, **timer_create**() returns 0, and the ID of the new timer is placed in **timerid*. On failure, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EAGAIN
Temporary error during kernel allocation of timer structures.

EINVAL
Clock ID, *sigev_notify*, *sigev_signo*, or *sigev_notify_thread_id* is invalid.

ENOMEM
Could not allocate memory.

ENOTSUP
The kernel does not support creating a timer against this *clockid*.

EPERM
clockid was **CLOCK_REALTIME_ALARM** or **CLOCK_BOOTTIME_ALARM** but the caller did not have the **CAP_WAKE_ALARM** capability.

VERSIONS

C library/kernel differences

Part of the implementation of the POSIX timers API is provided by glibc. In particular:

- Much of the functionality for **SIGEV_THREAD** is implemented within glibc, rather than the kernel. (This is necessarily so, since the thread involved in handling the notification is one that must be managed by the C library POSIX threads implementation.) Although the notification delivered to the process is via a thread, internally the NPTL implementation uses a *sigev_notify* value of **SIGEV_THREAD_ID** along with a real-time signal that is reserved by the implementation (see *nptl*(7)).
- The implementation of the default case where *evp* is NULL is handled inside glibc, which invokes the underlying system call with a suitably populated *sigevent* structure.
- The timer IDs presented at user level are maintained by glibc, which maps these IDs to the timer IDs employed by the kernel.

STANDARDS

POSIX.1-2008.

HISTORY

Linux 2.6. POSIX.1-2001.

Prior to Linux 2.6, glibc provided an incomplete user-space implementation (**CLOCK_REALTIME** timers only) using POSIX threads, and before glibc 2.17, the implementation falls back to this technique on systems running kernels older than Linux 2.6.

NOTES

A program may create multiple interval timers using **timer_create**().

Timers are not inherited by the child of a *fork*(2), and are disarmed and deleted during an *execve*(2).

The kernel preallocates a "queued real-time signal" for each timer created using **timer_create**(). Consequently, the number of timers is limited by the **RLIMIT_SIGPENDING** resource limit (see *setrlimit*(2)).

The timers created by **timer_create**() are commonly known as "POSIX (interval) timers". The POSIX timers API consists of the following interfaces:

timer_create()
: Create a timer.

timer_settime(2)
: Arm (start) or disarm (stop) a timer.

timer_gettime(2)
: Fetch the time remaining until the next expiration of a timer, along with the interval setting of the timer.

timer_getoverrun(2)
: Return the overrun count for the last timer expiration.

timer_delete(2)
: Disarm and delete a timer.

Since Linux 3.10, the */proc/*pid*/timers* file can be used to list the POSIX timers for the process with PID *pid*. See *proc*(5) for further information.

Since Linux 4.10, support for POSIX timers is a configurable option that is enabled by default. Kernel support can be disabled via the **CONFIG_POSIX_TIMERS** option.

EXAMPLES

The program below takes two arguments: a sleep period in seconds, and a timer frequency in nanoseconds. The program establishes a handler for the signal it uses for the timer, blocks that signal, creates and arms a timer that expires with the given frequency, sleeps for the specified number of seconds, and then unblocks the timer signal. Assuming that the timer expired at least once while the program slept, the signal handler will be invoked, and the handler displays some information about the timer notification. The program terminates after one invocation of the signal handler.

In the following example run, the program sleeps for 1 second, after creating a timer that has a frequency of 100 nanoseconds. By the time the signal is unblocked and delivered, there have been around ten million overruns.

```
$ ./a.out 1 100
Establishing handler for signal 34
Blocking signal 34
timer ID is 0x804c008
Sleeping for 1 seconds
Unblocking signal 34
Caught signal 34
    sival_ptr = 0xbfb174f4;     *sival_ptr = 0x804c008
    overrun count = 10004886
```

Program source

```

NAME

timer_delete − delete a POSIX per-process timer

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <time.h>

int timer_delete(timer_t *timerid***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

timer_delete():
_POSIX_C_SOURCE >= 199309L

DESCRIPTION

timer_delete() deletes the timer whose ID is given in *timerid*. If the timer was armed at the time of this call, it is disarmed before being deleted. The treatment of any pending signal generated by the deleted timer is unspecified.

RETURN VALUE

On success, **timer_delete**() returns 0. On failure, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL
timerid is not a valid timer ID.

STANDARDS

POSIX.1-2008.

HISTORY

Linux 2.6. POSIX.1-2001.

NAME

timer_getoverrun − get overrun count for a POSIX per-process timer

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <time.h>

int timer_getoverrun(timer_t *timerid***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

timer_getoverrun():
_POSIX_C_SOURCE >= 199309L

DESCRIPTION

timer_getoverrun() returns the "overrun count" for the timer referred to by *timerid*. An application can use the overrun count to accurately calculate the number of timer expirations that would have occurred over a given time interval. Timer overruns can occur both when receiving expiration notifications via signals (**SIGEV_SIGNAL**), and via threads (**SIGEV_THREAD**).

When expiration notifications are delivered via a signal, overruns can occur as follows. Regardless of whether or not a real-time signal is used for timer notifications, the system queues at most one signal per timer. (This is the behavior specified by POSIX.1. The alternative, queuing one signal for each timer expiration, could easily result in overflowing the allowed limits for queued signals on the system.) Because of system scheduling delays, or because the signal may be temporarily blocked, there can be a delay between the time when the notification signal is generated and the time when it is delivered (e.g., caught by a signal handler) or accepted (e.g., using *sigwaitinfo*(2)). In this interval, further timer expirations may occur. The timer overrun count is the number of additional timer expirations that occurred between the time when the signal was generated and when it was delivered or accepted.

Timer overruns can also occur when expiration notifications are delivered via invocation of a thread, since there may be an arbitrary delay between an expiration of the timer and the invocation of the notification thread, and in that delay interval, additional timer expirations may occur.

RETURN VALUE

On success, **timer_getoverrun**() returns the overrun count of the specified timer; this count may be 0 if no overruns have occurred. On failure, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL
timerid is not a valid timer ID.

VERSIONS

When timer notifications are delivered via signals (**SIGEV_SIGNAL**), on Linux it is also possible to obtain the overrun count via the *si_overrun* field of the *siginfo_t* structure (see *sigaction*(2)). This allows an application to avoid the overhead of making a system call to obtain the overrun count, but is a nonportable extension to POSIX.1.

POSIX.1 discusses timer overruns only in the context of timer notifications using signals.

STANDARDS

POSIX.1-2008.

HISTORY

Linux 2.6. POSIX.1-2001.

BUGS

POSIX.1 specifies that if the timer overrun count is equal to or greater than an implementation-defined maximum, **DELAYTIMER_MAX**, then **timer_getoverrun**() should return **DELAYTIMER_MAX**. However, before Linux 4.19, if the timer overrun value exceeds the maximum representable integer, the counter cycles, starting once more from low values. Since Linux 4.19, **timer_getoverrun**() returns **DELAYTIMER_MAX** (defined as **INT_MAX** in <*limits.h*>) in this case (and the overrun value is reset to 0).

EXAMPLES

See *timer_create*(2).

NAME

timer_settime, timer_gettime − arm/disarm and fetch state of POSIX per-process timer

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <time.h>

int timer_gettime(timer_t timerid, struct itimerspec *curr_value);
int timer_settime(timer_t timerid, int flags,
                  const struct itimerspec *restrict new_value,
                  struct itimerspec *_Nullable restrict old_value);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

timer_settime(), **timer_gettime**():
_POSIX_C_SOURCE >= 199309L

DESCRIPTION

timer_settime() arms or disarms the timer identified by *timerid*. The *new_value* argument is pointer to an *itimerspec* structure that specifies the new initial value and the new interval for the timer. The *itimerspec* structure is described in *itimerspec*(3type).

Each of the substructures of the *itimerspec* structure is a *timespec*(3) structure that allows a time value to be specified in seconds and nanoseconds. These time values are measured according to the clock that was specified when the timer was created by *timer_create*(2).

If *new_value−>it_value* specifies a nonzero value (i.e., either subfield is nonzero), then **timer_settime**() arms (starts) the timer, setting it to initially expire at the given time. (If the timer was already armed, then the previous settings are overwritten.) If *new_value−>it_value* specifies a zero value (i.e., both subfields are zero), then the timer is disarmed.

The *new_value−>it_interval* field specifies the period of the timer, in seconds and nanoseconds. If this field is nonzero, then each time that an armed timer expires, the timer is reloaded from the value specified in *new_value−>it_interval*. If *new_value−>it_interval* specifies a zero value, then the timer expires just once, at the time specified by *it_value*.

By default, the initial expiration time specified in *new_value−>it_value* is interpreted relative to the current time on the timer's clock at the time of the call. This can be modified by specifying **TIMER_ABSTIME** in *flags*, in which case *new_value−>it_value* is interpreted as an absolute value as measured on the timer's clock; that is, the timer will expire when the clock value reaches the value specified by *new_value−>it_value*. If the specified absolute time has already passed, then the timer expires immediately, and the overrun count (see *timer_getoverrun*(2)) will be set correctly.

If the value of the **CLOCK_REALTIME** clock is adjusted while an absolute timer based on that clock is armed, then the expiration of the timer will be appropriately adjusted. Adjustments to the **CLOCK_REALTIME** clock have no effect on relative timers based on that clock.

If *old_value* is not NULL, then it points to a buffer that is used to return the previous interval of the timer (in *old_value−>it_interval*) and the amount of time until the timer would previously have next expired (in *old_value−>it_value*).

timer_gettime() returns the time until next expiration, and the interval, for the timer specified by *timerid*, in the buffer pointed to by *curr_value*. The time remaining until the next timer expiration is returned in *curr_value−>it_value*; this is always a relative value, regardless of whether the **TIMER_ABSTIME** flag was used when arming the timer. If the value returned in *curr_value−>it_value* is zero, then the timer is currently disarmed. The timer interval is returned in *curr_value−>it_interval*. If the value returned in *curr_value−>it_interval* is zero, then this is a "one-shot" timer.

RETURN VALUE

On success, **timer_settime**() and **timer_gettime**() return 0. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

These functions may fail with the following errors:

EFAULT
new_value, *old_value*, or *curr_value* is not a valid pointer.

EINVAL
timerid is invalid.

timer_settime() may fail with the following errors:

EINVAL
new_value.it_value is negative; or *new_value.it_value.tv_nsec* is negative or greater than 999,999,999.

STANDARDS
POSIX.1-2008.

HISTORY

NAME

timerfd_create, timerfd_settime, timerfd_gettime − timers that notify via file descriptors

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/timerfd.h>

int timerfd_create(int clockid, int flags);

int timerfd_settime(int fd, int flags,
                    const struct itimerspec *new_value,
                    struct itimerspec *_Nullable old_value);
int timerfd_gettime(int fd, struct itimerspec *curr_value);
```

DESCRIPTION

These system calls create and operate on a timer that delivers timer expiration notifications via a file descriptor. They provide an alternative to the use of *setitimer*(2) or *timer_create*(2), with the advantage that the file descriptor may be monitored by *select*(2), *poll*(2), and *epoll*(7).

The use of these three system calls is analogous to the use of *timer_create*(2), *timer_settime*(2), and *timer_gettime*(2). (There is no analog of *timer_getoverrun*(2), since that functionality is provided by *read*(2), as described below.)

timerfd_create()

timerfd_create() creates a new timer object, and returns a file descriptor that refers to that timer. The *clockid* argument specifies the clock that is used to mark the progress of the timer, and must be one of the following:

CLOCK_REALTIME
: A settable system-wide real-time clock.

CLOCK_MONOTONIC
: A nonsettable monotonically increasing clock that measures time from some unspecified point in the past that does not change after system startup.

CLOCK_BOOTTIME (Since Linux 3.15)
: Like **CLOCK_MONOTONIC**, this is a monotonically increasing clock. However, whereas the **CLOCK_MONOTONIC** clock does not measure the time while a system is suspended, the **CLOCK_BOOTTIME** clock does include the time during which the system is suspended. This is useful for applications that need to be suspend-aware. **CLOCK_REALTIME** is not suitable for such applications, since that clock is affected by discontinuous changes to the system clock.

CLOCK_REALTIME_ALARM (since Linux 3.11)
: This clock is like **CLOCK_REALTIME**, but will wake the system if it is suspended. The caller must have the **CAP_WAKE_ALARM** capability in order to set a timer against this clock.

CLOCK_BOOTTIME_ALARM (since Linux 3.11)
: This clock is like **CLOCK_BOOTTIME**, but will wake the system if it is suspended. The caller must have the **CAP_WAKE_ALARM** capability in order to set a timer against this clock.

See *clock_getres*(2) for some further details on the above clocks.

The current value of each of these clocks can be retrieved using *clock_gettime*(2).

Starting with Linux 2.6.27, the following values may be bitwise ORed in *flags* to change the behavior of **timerfd_create**():

TFD_NONBLOCK
: Set the **O_NONBLOCK** file status flag on the open file description (see *open*(2)) referred to by the new file descriptor. Using this flag saves extra calls to *fcntl*(2) to achieve the same result.

TFD_CLOEXEC
Set the close-on-exec (**FD_CLOEXEC**) flag on the new file descriptor. See the description of the **O_CLOEXEC** flag in *open*(2) for reasons why this may be useful.

In Linux versions up to and including 2.6.26, *flags* must be specified as zero.

timerfd_settime()

timerfd_settime() arms (starts) or disarms (stops) the timer referred to by the file descriptor *fd*.

The *new_value* argument specifies the initial expiration and interval for the timer. The *itimerspec* structure used for this argument is described in *itimerspec*(3type).

new_value.it_value specifies the initial expiration of the timer, in seconds and nanoseconds. Setting either field of *new_value.it_value* to a nonzero value arms the timer. Setting both fields of *new_value.it_value* to zero disarms the timer.

Setting one or both fields of *new_value.it_interval* to nonzero values specifies the period, in seconds and nanoseconds, for repeated timer expirations after the initial expiration. If both fields of *new_value.it_interval* are zero, the timer expires just once, at the time specified by *new_value.it_value*.

By default, the initial expiration time specified in *new_value* is interpreted relative to the current time on the timer's clock at the time of the call (i.e., *new_value.it_value* specifies a time relative to the current value of the clock specified by *clockid*). An absolute timeout can be selected via the *flags* argument.

The *flags* argument is a bit mask that can include the following values:

TFD_TIMER_ABSTIME
Interpret *new_value.it_value* as an absolute value on the timer's clock. The timer will expire when the value of the timer's clock reaches the value specified in *new_value.it_value*.

TFD_TIMER_CANCEL_ON_SET
If this flag is specified along with **TFD_TIMER_ABSTIME** and the clock for this timer is **CLOCK_REALTIME** or **CLOCK_REALTIME_ALARM**, then mark this timer as cancelable if the real-time clock undergoes a discontinuous change (**settimeofday**(2), *clock_settime*(2), or similar). When such changes occur, a current or future *read*(2) from the file descriptor will fail with the error **ECANCELED**.

If the *old_value* argument is not NULL, then the *itimerspec* structure that it points to is used to return the setting of the timer that was current at the time of the call; see the description of **timerfd_gettime**() following.

timerfd_gettime()

timerfd_gettime() returns, in *curr_value*, an *itimerspec* structure that contains the current setting of the timer referred to by the file descriptor *fd*.

The *it_value* field returns the amount of time until the timer will next expire. If both fields of this structure are zero, then the timer is currently disarmed. This field always contains a relative value, regardless of whether the **TFD_TIMER_ABSTIME** flag was specified when setting the timer.

The *it_interval* field returns the interval of the timer. If both fields of this structure are zero, then the timer is set to expire just once, at the time specified by *curr_value.it_value*.

Operating on a timer file descriptor

The file descriptor returned by **timerfd_create**() supports the following additional operations:

read(2) If the timer has already expired one or more times since its settings were last modified using **timerfd_settime**(), or since the last successful *read*(2), then the buffer given to *read*(2) returns an unsigned 8-byte integer (*uint64_t*) containing the number of expirations that have occurred. (The returned value is in host byte order—that is, the native byte order for integers on the host machine.)

If no timer expirations have occurred at the time of the *read*(2), then the call either blocks until the next timer expiration, or fails with the error **EAGAIN** if the file descriptor has been made nonblocking (via the use of the *fcntl*(2) **F_SETFL** operation to set the **O_NONBLOCK** flag).

A *read*(2) fails with the error **EINVAL** if the size of the supplied buffer is less than 8 bytes.

If the associated clock is either **CLOCK_REALTIME** or **CLOCK_REALTIME_ALARM**, the timer is absolute (**TFD_TIMER_ABSTIME**), and the flag **TFD_TIMER_CANCEL_ON_SET** was specified when calling **timerfd_settime**(), then *read*(2) fails with the error **ECANCELED** if the real-time clock undergoes a discontinuous change. (This allows the reading application to discover such discontinuous changes to the clock.)

If the associated clock is either **CLOCK_REALTIME** or **CLOCK_REALTIME_ALARM**, the timer is absolute (**TFD_TIMER_ABSTIME**), and the flag **TFD_TIMER_CANCEL_ON_SET** was *not* specified when calling **timerfd_settime**(), then a discontinuous negative change to the clock (e.g., *clock_settime*(2)) may cause *read*(2) to unblock, but return a value of 0 (i.e., no bytes read), if the clock change occurs after the time expired, but before the *read*(2) on the file descriptor.

poll(2)
select(2)
(and similar)

The file descriptor is readable (the *select*(2) *readfds* argument; the *poll*(2) **POLLIN** flag) if one or more timer expirations have occurred.

The file descriptor also supports the other file-descriptor multiplexing APIs: *pselect*(2), *ppoll*(2), and *epoll*(7).

ioctl(2) The following timerfd-specific command is supported:

TFD_IOC_SET_TICKS (since Linux 3.17)

Adjust the number of timer expirations that have occurred. The argument is a pointer to a nonzero 8-byte integer (*uint64_t**) containing the new number of expirations. Once the number is set, any waiter on the timer is woken up. The only purpose of this command is to restore the expirations for the purpose of checkpoint/restore. This operation is available only if the kernel was configured with the **CONFIG_CHECKPOINT_RESTORE** option.

close(2)

When the file descriptor is no longer required it should be closed. When all file descriptors associated with the same timer object have been closed, the timer is disarmed and its resources are freed by the kernel.

fork(2) semantics

After a *fork*(2), the child inherits a copy of the file descriptor created by **timerfd_create**(). The file descriptor refers to the same underlying timer object as the corresponding file descriptor in the parent, and *read*(2)s in the child will return information about expirations of the timer.

execve(2) semantics

A file descriptor created by **timerfd_create**() is preserved across *execve*(2), and continues to generate timer expirations if the timer was armed.

RETURN VALUE

On success, **timerfd_create**() returns a new file descriptor. On error, −1 is returned and *errno* is set to indicate the error.

timerfd_settime() and **timerfd_gettime**() return 0 on success; on error they return −1, and set *errno* to indicate the error.

ERRORS

timerfd_create() can fail with the following errors:

EINVAL

The *clockid* is not valid.

EINVAL

flags is invalid; or, in Linux 2.6.26 or earlier, *flags* is nonzero.

EMFILE

The per-process limit on the number of open file descriptors has been reached.

ENFILE

The system-wide limit on the total number of open files has been reached.

ENODEV
Could not mount (internal) anonymous inode device.

ENOMEM
There was insufficient kernel memory to create the timer.

EPERM
clockid was **CLOCK_REALTIME_ALARM** or **CLOCK_BOOTTIME_ALARM** but the caller did not have the **CAP_WAKE_ALARM** capability.

timerfd_settime() and **timerfd_gettime**() can fail with the following errors:

EBADF
fd is not a valid file descriptor.

EFAULT
new_value, *old_value*, or *curr_value* is not a valid pointer.

EINVAL
fd is not a valid timerfd file descriptor.

timerfd_settime() can also fail with the following errors:

ECANCELED
See NOTES.

EINVAL
new_value is not properly initialized (one of the *tv_nsec* falls outside the range zero to 999,999,999).

EINVAL
flags is invalid.

STANDARDS
Linux.

HISTORY
Linux 2.6.25, glibc 2.8.

NOTES
Suppose the following scenario for **CLOCK_REALTIME** or **CLOCK_REALTIME_ALARM** timer that was created with **timerfd_create**():

(1) The timer has been started (**timerfd_settime**()) with the **TFD_TIMER_ABSTIME** and **TFD_TIMER_CANCEL_ON_SET** flags;

(2) A discontinuous change (e.g., *settimeofday*(2)) is subsequently made to the **CLOCK_REALTIME** clock; and

(3) the caller once more calls **timerfd_settime**() to rearm the timer (without first doing a *read*(2) on the file descriptor).

In this case the following occurs:

- The **timerfd_settime**() returns −1 with *errno* set to **ECANCELED**. (This enables the caller to know that the previous timer was affected by a discontinuous change to the clock.)
- The timer *is successfully rearmed* with the settings provided in the second **timerfd_settime**() call. (This was probably an implementation accident, but won't be fixed now, in case there are applications that depend on this behaviour.)

BUGS
Currently, **timerfd_create**() supports fewer types of clock IDs than *timer_create*(2).

EXAMPLES
The following program creates a timer and then monitors its progress. The program accepts up to three command-line arguments. The first argument specifies the number of seconds for the initial expiration of the timer. The second argument specifies the interval for the timer, in seconds. The third argument specifies the number of times the program should allow the timer to expire before terminating. The second and third command-line arguments are optional.

The following shell session demonstrates the use of the program:

```
$ a.out 3 1 100
0.000: timer started
3.000: read: 1; total=1
4.000: read: 1; total=2
^Z                  # type control-Z to suspend the program
[1]+  Stopped                 ./timerfd3_demo 3 1 100
$ fg                # Resume execution after a few seconds
a.out 3 1 100
9.660: read: 5; total=7
10.000: read: 1; total=8
11.000: read: 1; total=9
^C                  # type control-C to suspend the program
```

NAME

times − get process times

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/times.h>

clock_t times(struct tms * *buf* **);**

DESCRIPTION

times() stores the current process times in the *struct tms* that *buf* points to. The *struct tms* is as defined in <*sys/times.h*>:

```
struct tms {
    clock_t tms_utime;  /* user time */
    clock_t tms_stime;  /* system time */
    clock_t tms_cutime; /* user time of children */
    clock_t tms_cstime; /* system time of children */
};
```

The *tms_utime* field contains the CPU time spent executing instructions of the calling process. The *tms_stime* field contains the CPU time spent executing inside the kernel while performing tasks on behalf of the calling process.

The *tms_cutime* field contains the sum of the *tms_utime* and *tms_cutime* values for all waited-for terminated children. The *tms_cstime* field contains the sum of the *tms_stime* and *tms_cstime* values for all waited-for terminated children.

Times for terminated children (and their descendants) are added in at the moment *wait*(2) or *waitpid*(2) returns their process ID. In particular, times of grandchildren that the children did not wait for are never seen.

All times reported are in clock ticks.

RETURN VALUE

times() returns the number of clock ticks that have elapsed since an arbitrary point in the past. The return value may overflow the possible range of type *clock_t*. On error, *(clock_t) −1* is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT

tms points outside the process's address space.

VERSIONS

On Linux, the *buf* argument can be specified as NULL, with the result that **times**() just returns a function result. However, POSIX does not specify this behavior, and most other UNIX implementations require a non-NULL value for *buf*.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

In POSIX.1-1996 the symbol **CLK_TCK** (defined in <*time.h*>) is mentioned as obsolescent. It is obsolete now.

Before Linux 2.6.9, if the disposition of **SIGCHLD** is set to **SIG_IGN**, then the times of terminated children are automatically included in the *tms_cstime* and *tms_cutime* fields, although POSIX.1-2001 says that this should happen only if the calling process *wait*(2)s on its children. This nonconformance is rectified in Linux 2.6.9 and later.

On Linux, the "arbitrary point in the past" from which the return value of **times**() is measured has varied across kernel versions. On Linux 2.4 and earlier, this point is the moment the system was booted. Since Linux 2.6, this point is *(2^32/HZ) − 300* seconds before system boot time. This variability across kernel versions (and across UNIX implementations), combined with the fact that the returned value may overflow the range of *clock_t*, means that a portable application would be wise to avoid using this

value. To measure changes in elapsed time, use *clock_gettime*(2) instead.

SVr1-3 returns *long* and the struct members are of type *time_t* although they store clock ticks, not seconds since the Epoch. V7 used *long* for the struct members, because it had no type *time_t* yet.

NOTES

The number of clock ticks per second can be obtained using:

```
sysconf(_SC_CLK_TCK);
```

Note that *clock*(3) also returns a value of type *clock_t*, but this value is measured in units of **CLOCKS_PER_SEC**, not the clock ticks used by **times**().

BUGS

A limitation of the Linux system call conventions on some architectures (notably i386) means that on Linux 2.6 there is a small time window (41 seconds) soon after boot when **times**() can return −1, falsely indicating that an error occurred. The same problem can occur when the return value wraps past the maximum value that can be stored in **clock_t**.

NAME

tkill, tgkill − send a signal to a thread

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>          /* Definition of SIG* constants */
#include <sys/syscall.h>     /* Definition of SYS_* constants */
#include <unistd.h>

[[deprecated]] int syscall(SYS_tkill, pid_t tid, int sig);

#include <signal.h>

int tgkill(pid_t tgid, pid_t tid, int sig);
```

Note: glibc provides no wrapper for **tkill**(), necessitating the use of *syscall*(2).

DESCRIPTION

tgkill() sends the signal *sig* to the thread with the thread ID *tid* in the thread group *tgid*. (By contrast, *kill*(2) can be used to send a signal only to a process (i.e., thread group) as a whole, and the signal will be delivered to an arbitrary thread within that process.)

tkill() is an obsolete predecessor to **tgkill**(). It allows only the target thread ID to be specified, which may result in the wrong thread being signaled if a thread terminates and its thread ID is recycled. Avoid using this system call.

These are the raw system call interfaces, meant for internal thread library use.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EAGAIN
: The **RLIMIT_SIGPENDING** resource limit was reached and *sig* is a real-time signal.

EAGAIN
: Insufficient kernel memory was available and *sig* is a real-time signal.

EINVAL
: An invalid thread ID, thread group ID, or signal was specified.

EPERM
: Permission denied. For the required permissions, see *kill*(2).

ESRCH
: No process with the specified thread ID (and thread group ID) exists.

STANDARDS

Linux.

HISTORY

tkill() Linux 2.4.19 / 2.5.4.

tgkill() Linux 2.5.75, glibc 2.30.

NOTES

See the description of **CLONE_THREAD** in *clone*(2) for an explanation of thread groups.

SEE ALSO

clone(2), *gettid*(2), *kill*(2), *rt_sigqueueinfo*(2)

NAME

truncate, ftruncate − truncate a file to a specified length

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

int truncate(const char *path, off_t length);
int ftruncate(int  fd, off_t length);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

truncate():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L
|| /* glibc <= 2.19: */ _BSD_SOURCE

ftruncate():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.3.5: */ _POSIX_C_SOURCE >= 200112L
|| /* glibc <= 2.19: */ _BSD_SOURCE

DESCRIPTION

The **truncate**() and **ftruncate**() functions cause the regular file named by *path* or referenced by *fd* to be truncated to a size of precisely *length* bytes.

If the file previously was larger than this size, the extra data is lost. If the file previously was shorter, it is extended, and the extended part reads as null bytes ('\0').

The file offset is not changed.

If the size changed, then the st_ctime and st_mtime fields (respectively, time of last status change and time of last modification; see *inode*(7)) for the file are updated, and the set-user-ID and set-group-ID mode bits may be cleared.

With **ftruncate**(), the file must be open for writing; with **truncate**(), the file must be writable.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

For **truncate**():

EACCES
Search permission is denied for a component of the path prefix, or the named file is not writable by the user. (See also *path_resolution*(7).)

EFAULT
The argument *path* points outside the process's allocated address space.

EFBIG
The argument *length* is larger than the maximum file size. (XSI)

EINTR
While blocked waiting to complete, the call was interrupted by a signal handler; see *fcntl*(2) and *signal*(7).

EINVAL
The argument *length* is negative or larger than the maximum file size.

EIO An I/O error occurred updating the inode.

EISDIR
The named file is a directory.

ELOOP
Too many symbolic links were encountered in translating the pathname.

ENAMETOOLONG
A component of a pathname exceeded 255 characters, or an entire pathname exceeded 1023 characters.

ENOENT
The named file does not exist.

ENOTDIR
A component of the path prefix is not a directory.

EPERM
The underlying filesystem does not support extending a file beyond its current size.

EPERM
The operation was prevented by a file seal; see *fcntl*(2).

EROFS
The named file resides on a read-only filesystem.

ETXTBSY
The file is an executable file that is being executed.

For **ftruncate**() the same errors apply, but instead of things that can be wrong with *path*, we now have things that can be wrong with the file descriptor, *fd*:

EBADF
fd is not a valid file descriptor.

EBADF or **EINVAL**
fd is not open for writing.

EINVAL
fd does not reference a regular file or a POSIX shared memory object.

EINVAL or **EBADF**
The file descriptor *fd* is not open for writing. POSIX permits, and portable applications should handle, either error for this case. (Linux produces **EINVAL**.)

VERSIONS

The details in DESCRIPTION are for XSI-compliant systems. For non-XSI-compliant systems, the POSIX standard allows two behaviors for **ftruncate**() when *length* exceeds the file length (note that **truncate**() is not specified at all in such an environment): either returning an error, or extending the file. Like most UNIX implementations, Linux follows the XSI requirement when dealing with native filesystems. However, some nonnative filesystems do not permit **truncate**() and **ftruncate**() to be used to extend a file beyond its current length: a notable example on Linux is VFAT.

On some 32-bit architectures, the calling signature for these system calls differ, for the reasons described in *syscall*(2).

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.4BSD, SVr4 (first appeared in 4.2BSD).

The original Linux **truncate**() and **ftruncate**() system calls were not designed to handle large file offsets. Consequently, Linux 2.4 added **truncate64**() and **ftruncate64**() system calls that handle large files. However, these details can be ignored by applications using glibc, whose wrapper functions transparently employ the more recent system calls where they are available.

NOTES

ftruncate() can also be used to set the size of a POSIX shared memory object; see *shm_open*(3).

BUGS

A header file bug in glibc 2.12 meant that the minimum value of **_POSIX_C_SOURCE** required to expose the declaration of **ftruncate**() was 200809L instead of 200112L. This has been fixed in later glibc versions.

truncate(1), *open*(2), *stat*(2), *path_resolution*(7)

NAME

umask − set file mode creation mask

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/stat.h>

mode_t umask(mode_t *mask***);**

DESCRIPTION

umask() sets the calling process's file mode creation mask (umask) to *mask* & 0777 (i.e., only the file permission bits of *mask* are used), and returns the previous value of the mask.

The umask is used by *open*(2), *mkdir*(2), and other system calls that create files to modify the permissions placed on newly created files or directories. Specifically, permissions in the umask are turned off from the *mode* argument to *open*(2) and *mkdir*(2).

Alternatively, if the parent directory has a default ACL (see *acl*(5)), the umask is ignored, the default ACL is inherited, the permission bits are set based on the inherited ACL, and permission bits absent in the *mode* argument are turned off. For example, the following default ACL is equivalent to a umask of 022:

```
u::rwx,g::r-x,o::r-x
```

Combining the effect of this default ACL with a *mode* argument of 0666 (rw-rw-rw-), the resulting file permissions would be 0644 (rw-r--r--).

The constants that should be used to specify *mask* are described in *inode*(7).

The typical default value for the process umask is **S_IWGRP** | **S_IWOTH** (octal 022). In the usual case where the *mode* argument to *open*(2) is specified as:

```
S_IRUSR | S_IWUSR | S_IRGRP | S_IWGRP | S_IROTH | S_IWOTH
```

(octal 0666) when creating a new file, the permissions on the resulting file will be:

```
S_IRUSR | S_IWUSR | S_IRGRP | S_IROTH
```

(because 0666 & ~022 = 0644; i.e. rw−r−−r−−).

RETURN VALUE

This system call always succeeds and the previous value of the mask is returned.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

NOTES

A child process created via *fork*(2) inherits its parent's umask. The umask is left unchanged by *execve*(2).

It is impossible to use **umask**() to fetch a process's umask without at the same time changing it. A second call to **umask**() would then be needed to restore the umask. The nonatomicity of these two steps provides the potential for races in multithreaded programs.

Since Linux 4.7, the umask of any process can be viewed via the *Umask* field of */proc/*pid*/status*. Inspecting this field in */proc/self/status* allows a process to retrieve its umask without at the same time changing it.

The umask setting also affects the permissions assigned to POSIX IPC objects (**mq_open**(3), *sem_open*(3), *shm_open*(3)), FIFOs (**mkfifo**(3)), and UNIX domain sockets (**unix**(7)) created by the process. The umask does not affect the permissions assigned to System V IPC objects created by the process (using *msgget*(2), *semget*(2), *shmget*(2)).

SEE ALSO

chmod(2), *mkdir*(2), *open*(2), *stat*(2), *acl*(5)

NAME

umount, umount2 − unmount filesystem

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/mount.h>

int umount(const char *target);
int umount2(const char *target, int  flags);
```

DESCRIPTION

umount() and **umount2**() remove the attachment of the (topmost) filesystem mounted on *target*.

Appropriate privilege (Linux: the **CAP_SYS_ADMIN** capability) is required to unmount filesystems.

Linux 2.1.116 added the **umount2**() system call, which, like **umount**(), unmounts a target, but allows additional *flags* controlling the behavior of the operation:

MNT_FORCE (since Linux 2.1.116)
: Ask the filesystem to abort pending requests before attempting the unmount. This may allow the unmount to complete without waiting for an inaccessible server, but could cause data loss. If, after aborting requests, some processes still have active references to the filesystem, the unmount will still fail. As at Linux 4.12, **MNT_FORCE** is supported only on the following filesystems: 9p (since Linux 2.6.16), ceph (since Linux 2.6.34), cifs (since Linux 2.6.12), fuse (since Linux 2.6.16), lustre (since Linux 3.11), and NFS (since Linux 2.1.116).

MNT_DETACH (since Linux 2.4.11)
: Perform a lazy unmount: make the mount unavailable for new accesses, immediately disconnect the filesystem and all filesystems mounted below it from each other and from the mount table, and actually perform the unmount when the mount ceases to be busy.

MNT_EXPIRE (since Linux 2.6.8)
: Mark the mount as expired. If a mount is not currently in use, then an initial call to **umount2**() with this flag fails with the error **EAGAIN**, but marks the mount as expired. The mount remains expired as long as it isn't accessed by any process. A second **umount2**() call specifying **MNT_EXPIRE** unmounts an expired mount. This flag cannot be specified with either **MNT_FORCE** or **MNT_DETACH**.

UMOUNT_NOFOLLOW (since Linux 2.6.34)
: Don't dereference *target* if it is a symbolic link. This flag allows security problems to be avoided in set-user-ID-*root* programs that allow unprivileged users to unmount filesystems.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

The error values given below result from filesystem type independent errors. Each filesystem type may have its own special errors and its own special behavior. See the Linux kernel source code for details.

EAGAIN
: A call to **umount2**() specifying **MNT_EXPIRE** successfully marked an unbusy filesystem as expired.

EBUSY
: *target* could not be unmounted because it is busy.

EFAULT
: *target* points outside the user address space.

EINVAL
: *target* is not a mount point.

EINVAL
: *target* is locked; see *mount_namespaces*(7).

EINVAL
umount2() was called with **MNT_EXPIRE** and either **MNT_DETACH** or **MNT_FORCE**.

EINVAL (since Linux 2.6.34)
umount2() was called with an invalid flag value in *flags*.

ENAMETOOLONG
A pathname was longer than **MAXPATHLEN**.

ENOENT
A pathname was empty or had a nonexistent component.

ENOMEM
The kernel could not allocate a free page to copy filenames or data into.

EPERM
The caller does not have the required privileges.

STANDARDS
Linux.

HISTORY
MNT_DETACH and **MNT_EXPIRE** are available since glibc 2.11.

The original **umount**() function was called as *umount(device)* and would return **ENOTBLK** when called with something other than a block device. In Linux 0.98p4, a call *umount(dir)* was added, in order to support anonymous devices. In Linux 2.3.99-pre7, the call *umount(device)* was removed, leaving only *umount(dir)* (since now devices can be mounted in more than one place, so specifying the device does not suffice).

NOTES
umount() and shared mounts
Shared mounts cause any mount activity on a mount, including **umount**() operations, to be forwarded to every shared mount in the peer group and every slave mount of that peer group. This means that **umount**() of any peer in a set of shared mounts will cause all of its peers to be unmounted and all of their slaves to be unmounted as well.

This propagation of unmount activity can be particularly surprising on systems where every mount is shared by default. On such systems, recursively bind mounting the root directory of the filesystem onto a subdirectory and then later unmounting that subdirectory with **MNT_DETACH** will cause every mount in the mount namespace to be lazily unmounted.

To ensure **umount**() does not propagate in this fashion, the mount may be remounted using a *mount*(2) call with a *mount_flags* argument that includes both **MS_REC** and **MS_PRIVATE** prior to **umount**() being called.

SEE ALSO
mount(2), *mount_namespaces*(7), *path_resolution*(7), *mount*(8), *umount*(8)

NAME

uname − get name and information about current kernel

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/utsname.h>

int uname(struct utsname *****buf* **);

DESCRIPTION

uname() returns system information in the structure pointed to by *buf*. The *utsname* struct is defined in <*sys/utsname.h*>:

```
struct utsname {
    char sysname[];    /* Operating system name (e.g., "Linux") */
    char nodename[];   /* Name within communications network
                          to which the node is attached, if any */
    char release[];    /* Operating system release
                          (e.g., "2.6.28") */
    char version[];    /* Operating system version */
    char machine[];    /* Hardware type identifier */
#ifdef _GNU_SOURCE
    char domainname[]; /* NIS or YP domain name */
#endif
};
```

The length of the arrays in a *struct utsname* is unspecified (see NOTES); the fields are terminated by a null byte ('\0').

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT

buf is not valid.

VERSIONS

The *domainname* member (the NIS or YP domain name) is a GNU extension.

The length of the fields in the struct varies. Some operating systems or libraries use a hardcoded 9 or 33 or 65 or 257. Other systems use **SYS_NMLN** or **_SYS_NMLN** or **UTSLEN** or **_UTSNAME_LENGTH**. Clearly, it is a bad idea to use any of these constants; just use sizeof(...). SVr4 uses 257, "to support Internet hostnames" — this is the largest value likely to be encountered in the wild.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.4BSD.

C library/kernel differences

Over time, increases in the size of the *utsname* structure have led to three successive versions of **uname**(): *sys_olduname*() (slot *__NR_oldolduname*), *sys_uname*() (slot *__NR_olduname*), and *sys_newuname*() (slot *__NR_uname)*. The first one used length 9 for all fields; the second used 65; the third also uses 65 but adds the *domainname* field. The glibc **uname**() wrapper function hides these details from applications, invoking the most recent version of the system call provided by the kernel.

NOTES

The kernel has the name, release, version, and supported machine type built in. Conversely, the *nodename* field is configured by the administrator to match the network (this is what the BSD historically calls the "hostname", and is set via *sethostname*(2)). Similarly, the *domainname* field is set via *setdomainname*(2).

Part of the utsname information is also accessible via */proc/sys/kernel/*{*ostype*, *hostname*, *osrelease*, *version*, *domainname*}.

SEE ALSO

uname(1), *getdomainname*(2), *gethostname*(2), *uts_namespaces*(7)

NAME

afs_syscall, break, fattach, fdetach, ftime, getmsg, getpmsg, gtty, isastream, lock, madvise1, mpx, prof, profil, putmsg, putpmsg, security, stty, tuxcall, ulimit, vserver − unimplemented system calls

SYNOPSIS

Unimplemented system calls.

DESCRIPTION

These system calls are not implemented in the Linux kernel.

RETURN VALUE

These system calls always return −1 and set *errno* to **ENOSYS**.

NOTES

Note that *ftime*(3), *profil*(3), and *ulimit*(3) are implemented as library functions.

Some system calls, like *alloc_hugepages*(2), *free_hugepages*(2), *ioperm*(2), *iopl*(2), and *vm86*(2) exist only on certain architectures.

Some system calls, like *ipc*(2), *create_module*(2), *init_module*(2), and *delete_module*(2) exist only when the Linux kernel was built with support for them.

SEE ALSO

syscalls(2)

NAME

unlink, unlinkat − delete a name and possibly the file it refers to

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

int unlink(const char *pathname);

#include <fcntl.h>           /* Definition of AT_* constants */
#include <unistd.h>

int unlinkat(int dirfd, const char *pathname, int flags);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

unlinkat():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_ATFILE_SOURCE

DESCRIPTION

unlink() deletes a name from the filesystem. If that name was the last link to a file and no processes have the file open, the file is deleted and the space it was using is made available for reuse.

If the name was the last link to a file but any processes still have the file open, the file will remain in existence until the last file descriptor referring to it is closed.

If the name referred to a symbolic link, the link is removed.

If the name referred to a socket, FIFO, or device, the name for it is removed but processes which have the object open may continue to use it.

unlinkat()

The **unlinkat**() system call operates in exactly the same way as either **unlink**() or *rmdir*(2) (depending on whether or not *flags* includes the **AT_REMOVEDIR** flag) except for the differences described here.

If the pathname given in *pathname* is relative, then it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by **unlink**() and *rmdir*(2) for a relative pathname).

If the pathname given in *pathname* is relative and *dirfd* is the special value **AT_FDCWD**, then *pathname* is interpreted relative to the current working directory of the calling process (like **unlink**() and *rmdir*(2)).

If the pathname given in *pathname* is absolute, then *dirfd* is ignored.

flags is a bit mask that can either be specified as 0, or by ORing together flag values that control the operation of **unlinkat**(). Currently, only one such flag is defined:

AT_REMOVEDIR
By default, **unlinkat**() performs the equivalent of **unlink**() on *pathname*. If the **AT_REMOVEDIR** flag is specified, it performs the equivalent of *rmdir*(2) on *pathname*.

See *openat*(2) for an explanation of the need for **unlinkat**().

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EACCES
Write access to the directory containing *pathname* is not allowed for the process's effective UID, or one of the directories in *pathname* did not allow search permission. (See also *path_resolution*(7).)

EBUSY
The file *pathname* cannot be unlinked because it is being used by the system or another process; for example, it is a mount point or the NFS client software created it to represent an active but otherwise nameless inode ("NFS silly renamed").

EFAULT
pathname points outside your accessible address space.

EIO An I/O error occurred.

EISDIR
pathname refers to a directory. (This is the non-POSIX value returned since Linux 2.1.132.)

ELOOP
Too many symbolic links were encountered in translating *pathname*.

ENAMETOOLONG
pathname was too long.

ENOENT
A component in *pathname* does not exist or is a dangling symbolic link, or *pathname* is empty.

ENOMEM
Insufficient kernel memory was available.

ENOTDIR
A component used as a directory in *pathname* is not, in fact, a directory.

EPERM
The system does not allow unlinking of directories, or unlinking of directories requires privileges that the calling process doesn't have. (This is the POSIX prescribed error return; as noted above, Linux returns **EISDIR** for this case.)

EPERM (Linux only)
The filesystem does not allow unlinking of files.

EPERM or **EACCES**
The directory containing *pathname* has the sticky bit (**S_ISVTX**) set and the process's effective UID is neither the UID of the file to be deleted nor that of the directory containing it, and the process is not privileged (Linux: does not have the **CAP_FOWNER** capability).

EPERM
The file to be unlinked is marked immutable or append-only. (See *ioctl_iflags*(2).)

EROFS
pathname refers to a file on a read-only filesystem.

The same errors that occur for **unlink**() and *rmdir*(2) can also occur for **unlinkat**(). The following additional errors can occur for **unlinkat**():

EBADF
pathname is relative but *dirfd* is neither **AT_FDCWD** nor a valid file descriptor.

EINVAL
An invalid flag value was specified in *flags*.

EISDIR
pathname refers to a directory, and **AT_REMOVEDIR** was not specified in *flags*.

ENOTDIR
pathname is relative and *dirfd* is a file descriptor referring to a file other than a directory.

STANDARDS
POSIX.1-2008.

HISTORY
unlink()
SVr4, 4.3BSD, POSIX.1-2001.

unlinkat()
POSIX.1-2008. Linux 2.6.16, glibc 2.4.

glibc
On older kernels where **unlinkat**() is unavailable, the glibc wrapper function falls back to the use of **unlink**() or *rmdir*(2). When *pathname* is a relative pathname, glibc constructs a pathname based on the symbolic link in */proc/self/fd* that corresponds to the *dirfd* argument.

BUGS

Infelicities in the protocol underlying NFS can cause the unexpected disappearance of files which are still being used.

SEE ALSO

rm(1), *unlink*(1), *chmod*(2), *link*(2), *mknod*(2), *open*(2), *rename*(2), *rmdir*(2), *mkfifo*(3), *remove*(3), *path_resolution*(7), *symlink*(7)

NAME

unshare − disassociate parts of the process execution context

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE
#include <sched.h>

int unshare(int flags);
```

DESCRIPTION

unshare() allows a process (or thread) to disassociate parts of its execution context that are currently being shared with other processes (or threads). Part of the execution context, such as the mount namespace, is shared implicitly when a new process is created using *fork*(2) or *vfork*(2), while other parts, such as virtual memory, may be shared by explicit request when creating a process or thread using *clone*(2).

The main use of **unshare**() is to allow a process to control its shared execution context without creating a new process.

The *flags* argument is a bit mask that specifies which parts of the execution context should be unshared. This argument is specified by ORing together zero or more of the following constants:

CLONE_FILES
: Reverse the effect of the *clone*(2) **CLONE_FILES** flag. Unshare the file descriptor table, so that the calling process no longer shares its file descriptors with any other process.

CLONE_FS
: Reverse the effect of the *clone*(2) **CLONE_FS** flag. Unshare filesystem attributes, so that the calling process no longer shares its root directory (**chroot**(2)), current directory (**chdir**(2)), or umask (**umask**(2)) attributes with any other process.

CLONE_NEWCGROUP (since Linux 4.6)
: This flag has the same effect as the *clone*(2) **CLONE_NEWCGROUP** flag. Unshare the cgroup namespace. Use of **CLONE_NEWCGROUP** requires the **CAP_SYS_ADMIN** capability.

CLONE_NEWIPC (since Linux 2.6.19)
: This flag has the same effect as the *clone*(2) **CLONE_NEWIPC** flag. Unshare the IPC namespace, so that the calling process has a private copy of the IPC namespace which is not shared with any other process. Specifying this flag automatically implies **CLONE_SYSVSEM** as well. Use of **CLONE_NEWIPC** requires the **CAP_SYS_ADMIN** capability.

CLONE_NEWNET (since Linux 2.6.24)
: This flag has the same effect as the *clone*(2) **CLONE_NEWNET** flag. Unshare the network namespace, so that the calling process is moved into a new network namespace which is not shared with any previously existing process. Use of **CLONE_NEWNET** requires the **CAP_SYS_ADMIN** capability.

CLONE_NEWNS
: This flag has the same effect as the *clone*(2) **CLONE_NEWNS** flag. Unshare the mount namespace, so that the calling process has a private copy of its namespace which is not shared with any other process. Specifying this flag automatically implies **CLONE_FS** as well. Use of **CLONE_NEWNS** requires the **CAP_SYS_ADMIN** capability. For further information, see *mount_namespaces*(7).

CLONE_NEWPID (since Linux 3.8)
: This flag has the same effect as the *clone*(2) **CLONE_NEWPID** flag. Unshare the PID namespace, so that the calling process has a new PID namespace for its children which is not shared with any previously existing process. The calling process is *not* moved into the new namespace. The first child created by the calling process will have the process ID 1 and will assume the role of *init*(1) in the new namespace. **CLONE_NEWPID** automatically implies **CLONE_THREAD** as well. Use of **CLONE_NEWPID** requires the **CAP_SYS_ADMIN** capability. For further information, see *pid_namespaces*(7).

CLONE_NEWTIME (since Linux 5.6)
Unshare the time namespace, so that the calling process has a new time namespace for its children which is not shared with any previously existing process. The calling process is *not* moved into the new namespace. Use of **CLONE_NEWTIME** requires the **CAP_SYS_ADMIN** capability. For further information, see *time_namespaces*(7).

CLONE_NEWUSER (since Linux 3.8)
This flag has the same effect as the *clone*(2) **CLONE_NEWUSER** flag. Unshare the user namespace, so that the calling process is moved into a new user namespace which is not shared with any previously existing process. As with the child process created by *clone*(2) with the **CLONE_NEWUSER** flag, the caller obtains a full set of capabilities in the new namespace.

CLONE_NEWUSER requires that the calling process is not threaded; specifying **CLONE_NEWUSER** automatically implies **CLONE_THREAD**. Since Linux 3.9, **CLONE_NEWUSER** also automatically implies **CLONE_FS**. **CLONE_NEWUSER** requires that the user ID and group ID of the calling process are mapped to user IDs and group IDs in the user namespace of the calling process at the time of the call.

For further information on user namespaces, see *user_namespaces*(7).

CLONE_NEWUTS (since Linux 2.6.19)
This flag has the same effect as the *clone*(2) **CLONE_NEWUTS** flag. Unshare the UTS IPC namespace, so that the calling process has a private copy of the UTS namespace which is not shared with any other process. Use of **CLONE_NEWUTS** requires the **CAP_SYS_ADMIN** capability.

CLONE_SYSVSEM (since Linux 2.6.26)
This flag reverses the effect of the *clone*(2) **CLONE_SYSVSEM** flag. Unshare System V semaphore adjustment (*semadj*) values, so that the calling process has a new empty *semadj* list that is not shared with any other process. If this is the last process that has a reference to the process's current *semadj* list, then the adjustments in that list are applied to the corresponding semaphores, as described in *semop*(2).

In addition, **CLONE_THREAD**, **CLONE_SIGHAND**, and **CLONE_VM** can be specified in *flags* if the caller is single threaded (i.e., it is not sharing its address space with another process or thread). In this case, these flags have no effect. (Note also that specifying **CLONE_THREAD** automatically implies **CLONE_VM**, and specifying **CLONE_VM** automatically implies **CLONE_SIGHAND**.) If the process is multithreaded, then the use of these flags results in an error.

If *flags* is specified as zero, then **unshare**() is a no-op; no changes are made to the calling process's execution context.

RETURN VALUE

On success, zero returned. On failure, −1 is returned and *errno* is set to indicate the error.

ERRORS

EINVAL
An invalid bit was specified in *flags*.

EINVAL
CLONE_THREAD, **CLONE_SIGHAND**, or **CLONE_VM** was specified in *flags*, and the caller is multithreaded.

EINVAL
CLONE_NEWIPC was specified in *flags*, but the kernel was not configured with the **CONFIG_SYSVIPC** and **CONFIG_IPC_NS** options.

EINVAL
CLONE_NEWNET was specified in *flags*, but the kernel was not configured with the **CONFIG_NET_NS** option.

EINVAL
CLONE_NEWPID was specified in *flags*, but the kernel was not configured with the **CONFIG_PID_NS** option.

EINVAL
CLONE_NEWUSER was specified in *flags*, but the kernel was not configured with the **CONFIG_USER_NS** option.

EINVAL
CLONE_NEWUTS was specified in *flags*, but the kernel was not configured with the **CONFIG_UTS_NS** option.

EINVAL
CLONE_NEWPID was specified in *flags*, but the process has previously called **unshare**() with the **CLONE_NEWPID** flag.

ENOMEM
Cannot allocate sufficient memory to copy parts of caller's context that need to be unshared.

ENOSPC (since Linux 3.7)
CLONE_NEWPID was specified in flags, but the limit on the nesting depth of PID namespaces would have been exceeded; see *pid_namespaces*(7).

ENOSPC (since Linux 4.9; beforehand **EUSERS**)
CLONE_NEWUSER was specified in *flags*, and the call would cause the limit on the number of nested user namespaces to be exceeded. See *user_namespaces*(7).

From Linux 3.11 to Linux 4.8, the error diagnosed in this case was **EUSERS**.

ENOSPC (since Linux 4.9)
One of the values in *flags* specified the creation of a new user namespace, but doing so would have caused the limit defined by the corresponding file in */proc/sys/user* to be exceeded. For further details, see *namespaces*(7).

EPERM
The calling process did not have the required privileges for this operation.

EPERM
CLONE_NEWUSER was specified in *flags*, but either the effective user ID or the effective group ID of the caller does not have a mapping in the parent namespace (see *user_namespaces*(7)).

EPERM (since Linux 3.9)
CLONE_NEWUSER was specified in *flags* and the caller is in a chroot environment (i.e., the caller's root directory does not match the root directory of the mount namespace in which it resides).

EUSERS (from Linux 3.11 to Linux 4.8)
CLONE_NEWUSER was specified in *flags*, and the limit on the number of nested user namespaces would be exceeded. See the discussion of the **ENOSPC** error above.

STANDARDS
Linux.

HISTORY
Linux 2.6.16.

NOTES
Not all of the process attributes that can be shared when a new process is created using *clone*(2) can be unshared using **unshare**(). In particular, as at kernel 3.8, **unshare**() does not implement flags that reverse the effects of **CLONE_SIGHAND**, **CLONE_THREAD**, or **CLONE_VM**. Such functionality may be added in the future, if required.

Creating all kinds of namespace, except user namespaces, requires the **CAP_SYS_ADMIN** capability. However, since creating a user namespace automatically confers a full set of capabilities, creating both a user namespace and any other type of namespace in the same **unshare**() call does not require the **CAP_SYS_ADMIN** capability in the original namespace.

EXAMPLES
The program below provides a simple implementation of the *unshare*(1) command, which unshares one or more namespaces and executes the command supplied in its command-line arguments. Here's an example of the use of this program, running a shell in a new mount namespace, and verifying that the

original shell and the new shell are in separate mount namespaces:

```
$ readlink /proc/$$/ns/mnt
mnt:[4026531840]
$ sudo ./unshare −m /bin/bash
# readlink /proc/$$/ns/mnt
mnt:[4026532325]
```

The differing output of the two *readlink*(1) commands shows that the two shells are in different mount namespaces.

NAME

uselib − load shared library

SYNOPSIS

#include <unistd.h>

[[deprecated]] int uselib(const char ****library*);**

DESCRIPTION

The system call **uselib**() serves to load a shared library to be used by the calling process. It is given a pathname. The address where to load is found in the library itself. The library can have any recognized binary format.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

In addition to all of the error codes returned by *open*(2) and *mmap*(2), the following may also be returned:

EACCES
: The library specified by *library* does not have read or execute permission, or the caller does not have search permission for one of the directories in the path prefix. (See also *path_resolution*(7).)

ENFILE
: The system-wide limit on the total number of open files has been reached.

ENOEXEC
: The file specified by *library* is not an executable of a known type; for example, it does not have the correct magic numbers.

STANDARDS

Linux.

HISTORY

This obsolete system call is not supported by glibc. No declaration is provided in glibc headers, but, through a quirk of history, glibc before glibc 2.23 did export an ABI for this system call. Therefore, in order to employ this system call, it was sufficient to manually declare the interface in your code; alternatively, you could invoke the system call using *syscall*(2).

In ancient libc versions (before glibc 2.0), **uselib**() was used to load the shared libraries with names found in an array of names in the binary.

Since Linux 3.15, this system call is available only when the kernel is configured with the **CONFIG_USELIB** option.

NAME

userfaultfd − create a file descriptor for handling page faults in user space

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <fcntl.h>            /* Definition of O_* constants */
#include <sys/syscall.h>      /* Definition of SYS_* constants */
#include <linux/userfaultfd.h> /* Definition of UFFD_* constants */
#include <unistd.h>

int syscall(SYS_userfaultfd, int flags);
```

Note: glibc provides no wrapper for **userfaultfd**(), necessitating the use of *syscall*(2).

DESCRIPTION

userfaultfd() creates a new userfaultfd object that can be used for delegation of page-fault handling to a user-space application, and returns a file descriptor that refers to the new object. The new userfaultfd object is configured using *ioctl*(2).

Once the userfaultfd object is configured, the application can use *read*(2) to receive userfaultfd notifications. The reads from userfaultfd may be blocking or non-blocking, depending on the value of *flags* used for the creation of the userfaultfd or subsequent calls to *fcntl*(2).

The following values may be bitwise ORed in *flags* to change the behavior of **userfaultfd**():

O_CLOEXEC
: Enable the close-on-exec flag for the new userfaultfd file descriptor. See the description of the **O_CLOEXEC** flag in *open*(2).

O_NONBLOCK
: Enables non-blocking operation for the userfaultfd object. See the description of the **O_NONBLOCK** flag in *open*(2).

UFFD_USER_MODE_ONLY
: This is an userfaultfd-specific flag that was introduced in Linux 5.11. When set, the userfaultfd object will only be able to handle page faults originated from the user space on the registered regions. When a kernel-originated fault was triggered on the registered range with this userfaultfd, a **SIGBUS** signal will be delivered.

When the last file descriptor referring to a userfaultfd object is closed, all memory ranges that were registered with the object are unregistered and unread events are flushed.

Userfaultfd supports three modes of registration:

UFFDIO_REGISTER_MODE_MISSING (since Linux 4.10)
: When registered with **UFFDIO_REGISTER_MODE_MISSING** mode, user-space will receive a page-fault notification when a missing page is accessed. The faulted thread will be stopped from execution until the page fault is resolved from user-space by either an **UFFDIO_COPY** or an **UFFDIO_ZEROPAGE** ioctl.

UFFDIO_REGISTER_MODE_MINOR (since Linux 5.13)
: When registered with **UFFDIO_REGISTER_MODE_MINOR** mode, user-space will receive a page-fault notification when a minor page fault occurs. That is, when a backing page is in the page cache, but page table entries don't yet exist. The faulted thread will be stopped from execution until the page fault is resolved from user-space by an **UFFDIO_CONTINUE** ioctl.

UFFDIO_REGISTER_MODE_WP (since Linux 5.7)
: When registered with **UFFDIO_REGISTER_MODE_WP** mode, user-space will receive a page-fault notification when a write-protected page is written. The faulted thread will be stopped from execution until user-space write-unprotects the page using an **UFFDIO_WRITEPROTECT** ioctl.

Multiple modes can be enabled at the same time for the same memory range.

Since Linux 4.14, a userfaultfd page-fault notification can selectively embed faulting thread ID information into the notification. One needs to enable this feature explicitly using the

UFFD_FEATURE_THREAD_ID feature bit when initializing the userfaultfd context. By default, thread ID reporting is disabled.

Usage

The userfaultfd mechanism is designed to allow a thread in a multithreaded program to perform user-space paging for the other threads in the process. When a page fault occurs for one of the regions registered to the userfaultfd object, the faulting thread is put to sleep and an event is generated that can be read via the userfaultfd file descriptor. The fault-handling thread reads events from this file descriptor and services them using the operations described in *ioctl_userfaultfd*(2). When servicing the page fault events, the fault-handling thread can trigger a wake-up for the sleeping thread.

It is possible for the faulting threads and the fault-handling threads to run in the context of different processes. In this case, these threads may belong to different programs, and the program that executes the faulting threads will not necessarily cooperate with the program that handles the page faults. In such non-cooperative mode, the process that monitors userfaultfd and handles page faults needs to be aware of the changes in the virtual memory layout of the faulting process to avoid memory corruption.

Since Linux 4.11, userfaultfd can also notify the fault-handling threads about changes in the virtual memory layout of the faulting process. In addition, if the faulting process invokes *fork*(2), the userfaultfd objects associated with the parent may be duplicated into the child process and the userfaultfd monitor will be notified (via the **UFFD_EVENT_FORK** described below) about the file descriptor associated with the userfault objects created for the child process, which allows the userfaultfd monitor to perform user-space paging for the child process. Unlike page faults which have to be synchronous and require an explicit or implicit wakeup, all other events are delivered asynchronously and the non-cooperative process resumes execution as soon as the userfaultfd manager executes *read*(2). The userfaultfd manager should carefully synchronize calls to **UFFDIO_COPY** with the processing of events.

The current asynchronous model of the event delivery is optimal for single threaded non-cooperative userfaultfd manager implementations.

Since Linux 5.7, userfaultfd is able to do synchronous page dirty tracking using the new write-protect register mode. One should check against the feature bit **UFFD_FEATURE_PAGEFAULT_FLAG_WP** before using this feature. Similar to the original userfaultfd missing mode, the write-protect mode will generate a userfaultfd notification when the protected page is written. The user needs to resolve the page fault by unprotecting the faulted page and kicking the faulted thread to continue. For more information, please refer to the "Userfaultfd write-protect mode" section.

Userfaultfd operation

After the userfaultfd object is created with **userfaultfd**(), the application must enable it using the **UFFDIO_API** *ioctl*(2) operation. This operation allows a two-step handshake between the kernel and user space to determine what API version and features the kernel supports, and then to enable those features user space wants. This operation must be performed before any of the other *ioctl*(2) operations described below (or those operations fail with the **EINVAL** error).

After a successful **UFFDIO_API** operation, the application then registers memory address ranges using the **UFFDIO_REGISTER** *ioctl*(2) operation. After successful completion of a **UFFDIO_REGISTER** operation, a page fault occurring in the requested memory range, and satisfying the mode defined at the registration time, will be forwarded by the kernel to the user-space application. The application can then use various (e.g., **UFFDIO_COPY**, **UFFDIO_ZEROPAGE**, or **UFFDIO_CONTINUE**) *ioctl*(2) operations to resolve the page fault.

Since Linux 4.14, if the application sets the **UFFD_FEATURE_SIGBUS** feature bit using the **UFFDIO_API** *ioctl*(2), no page-fault notification will be forwarded to user space. Instead a **SIGBUS** signal is delivered to the faulting process. With this feature, userfaultfd can be used for robustness purposes to simply catch any access to areas within the registered address range that do not have pages allocated, without having to listen to userfaultfd events. No userfaultfd monitor will be required for dealing with such memory accesses. For example, this feature can be useful for applications that want to prevent the kernel from automatically allocating pages and filling holes in sparse files when the hole is accessed through a memory mapping.

The **UFFD_FEATURE_SIGBUS** feature is implicitly inherited through *fork*(2) if used in combination with **UFFD_FEATURE_FORK**.

Details of the various *ioctl*(2) operations can be found in *ioctl_userfaultfd*(2).

Since Linux 4.11, events other than page-fault may enabled during **UFFDIO_API** operation.

Up to Linux 4.11, userfaultfd can be used only with anonymous private memory mappings. Since Linux 4.11, userfaultfd can be also used with hugetlbfs and shared memory mappings.

Userfaultfd write-protect mode (since Linux 5.7)

Since Linux 5.7, userfaultfd supports write-protect mode for anonymous memory. The user needs to first check availability of this feature using **UFFDIO_API** ioctl against the feature bit **UFFD_FEATURE_PAGEFAULT_FLAG_WP** before using this feature.

Since Linux 5.19, the write-protection mode was also supported on shmem and hugetlbfs memory types. It can be detected with the feature bit **UFFD_FEATURE_WP_HUGETLBFS_SHMEM**.

To register with userfaultfd write-protect mode, the user needs to initiate the **UFFDIO_REGISTER** ioctl with mode **UFFDIO_REGISTER_MODE_WP** set. Note that it is legal to monitor the same memory range with multiple modes. For example, the user can do **UFFDIO_REGISTER** with the mode set to **UFFDIO_REGISTER_MODE_MISSING | UFFDIO_REGISTER_MODE_WP**. When there is only **UFFDIO_REGISTER_MODE_WP** registered, user-space will *not* receive any notification when a missing page is written. Instead, user-space will receive a write-protect page-fault notification only when an existing but write-protected page got written.

After the **UFFDIO_REGISTER** ioctl completed with **UFFDIO_REGISTER_MODE_WP** mode set, the user can write-protect any existing memory within the range using the ioctl **UFFDIO_WRITEPROTECT** where *uffdio_writeprotect.mode* should be set to **UFFDIO_WRITEPROTECT_MODE_WP**.

When a write-protect event happens, user-space will receive a page-fault notification whose *uffd_msg.pagefault.flags* will be with **UFFD_PAGEFAULT_FLAG_WP** flag set. Note: since only writes can trigger this kind of fault, write-protect notifications will always have the **UFFD_PAGEFAULT_FLAG_WRITE** bit set along with the **UFFD_PAGEFAULT_FLAG_WP** bit.

To resolve a write-protection page fault, the user should initiate another **UFFDIO_WRITEPROTECT** ioctl, whose *uffd_msg.pagefault.flags* should have the flag **UFFDIO_WRITEPROTECT_MODE_WP** cleared upon the faulted page or range.

Userfaultfd minor fault mode (since Linux 5.13)

Since Linux 5.13, userfaultfd supports minor fault mode. In this mode, fault messages are produced not for major faults (where the page was missing), but rather for minor faults, where a page exists in the page cache, but the page table entries are not yet present. The user needs to first check availability of this feature using the **UFFDIO_API** ioctl with the appropriate feature bits set before using this feature: **UFFD_FEATURE_MINOR_HUGETLBFS** since Linux 5.13, or **UFFD_FEATURE_MINOR_SHMEM** since Linux 5.14.

To register with userfaultfd minor fault mode, the user needs to initiate the **UFFDIO_REGISTER** ioctl with mode **UFFD_REGISTER_MODE_MINOR** set.

When a minor fault occurs, user-space will receive a page-fault notification whose *uffd_msg.pagefault.flags* will have the **UFFD_PAGEFAULT_FLAG_MINOR** flag set.

To resolve a minor page fault, the handler should decide whether or not the existing page contents need to be modified first. If so, this should be done in-place via a second, non-userfaultfd-registered mapping to the same backing page (e.g., by mapping the shmem or hugetlbfs file twice). Once the page is considered "up to date", the fault can be resolved by initiating an **UFFDIO_CONTINUE** ioctl, which installs the page table entries and (by default) wakes up the faulting thread(s).

Minor fault mode supports only hugetlbfs-backed (since Linux 5.13) and shmem-backed (since Linux 5.14) memory.

Reading from the userfaultfd structure

Each *read*(2) from the userfaultfd file descriptor returns one or more *uffd_msg* structures, each of which describes a page-fault event or an event required for the non-cooperative userfaultfd usage:

```
struct uffd_msg {
    __u8  event;            /* Type of event */
    ...
    union {
        struct {
```

```
                __u64 flags;    /* Flags describing fault */
                __u64 address;  /* Faulting address */
                union {
                    __u32 ptid; /* Thread ID of the fault */
                } feat;
            } pagefault;

            struct {            /* Since Linux 4.11 */
                __u32 ufd;      /* Userfault file descriptor
                                   of the child process */
            } fork;

            struct {            /* Since Linux 4.11 */
                __u64 from;     /* Old address of remapped area */
                __u64 to;       /* New address of remapped area */
                __u64 len;      /* Original mapping length */
            } remap;

            struct {            /* Since Linux 4.11 */
                __u64 start;    /* Start address of removed area */
                __u64 end;      /* End address of removed area */
            } remove;
            ...
        } arg;

        /* Padding fields omitted */
    } __packed;
```

If multiple events are available and the supplied buffer is large enough, *read*(2) returns as many events as will fit in the supplied buffer. If the buffer supplied to *read*(2) is smaller than the size of the *uffd_msg* structure, the *read*(2) fails with the error **EINVAL**.

The fields set in the *uffd_msg* structure are as follows:

event The type of event. Depending of the event type, different fields of the *arg* union represent details required for the event processing. The non-page-fault events are generated only when appropriate feature is enabled during API handshake with **UFFDIO_API** *ioctl*(2).

The following values can appear in the *event* field:

UFFD_EVENT_PAGEFAULT (since Linux 4.3)
A page-fault event. The page-fault details are available in the *pagefault* field.

UFFD_EVENT_FORK (since Linux 4.11)
Generated when the faulting process invokes *fork*(2) (or *clone*(2) without the **CLONE_VM** flag). The event details are available in the *fork* field.

UFFD_EVENT_REMAP (since Linux 4.11)
Generated when the faulting process invokes *mremap*(2). The event details are available in the *remap* field.

UFFD_EVENT_REMOVE (since Linux 4.11)
Generated when the faulting process invokes *madvise*(2) with **MADV_DONTNEED** or **MADV_REMOVE** advice. The event details are available in the *remove* field.

UFFD_EVENT_UNMAP (since Linux 4.11)
Generated when the faulting process unmaps a memory range, either explicitly using *munmap*(2) or implicitly during *mmap*(2) or *mremap*(2). The event details are available in the *remove* field.

pagefault.address
The address that triggered the page fault.

pagefault.flags
A bit mask of flags that describe the event. For **UFFD_EVENT_PAGEFAULT**, the following flag may appear:

UFFD_PAGEFAULT_FLAG_WP
If this flag is set, then the fault was a write-protect fault.

UFFD_PAGEFAULT_FLAG_MINOR
If this flag is set, then the fault was a minor fault.

UFFD_PAGEFAULT_FLAG_WRITE
If this flag is set, then the fault was a write fault.

If neither **UFFD_PAGEFAULT_FLAG_WP** nor **UFFD_PAGEFAULT_FLAG_MINOR** are set, then the fault was a missing fault.

pagefault.feat.pid
The thread ID that triggered the page fault.

fork.ufd
The file descriptor associated with the userfault object created for the child created by *fork*(2).

remap.from
The original address of the memory range that was remapped using *mremap*(2).

remap.to
The new address of the memory range that was remapped using *mremap*(2).

remap.len
The original length of the memory range that was remapped using *mremap*(2).

remove.start
The start address of the memory range that was freed using *madvise*(2) or unmapped

remove.end
The end address of the memory range that was freed using *madvise*(2) or unmapped

A *read*(2) on a userfaultfd file descriptor can fail with the following errors:

EINVAL
The userfaultfd object has not yet been enabled using the **UFFDIO_API** *ioctl*(2) operation

If the **O_NONBLOCK** flag is enabled in the associated open file description, the userfaultfd file descriptor can be monitored with *poll*(2), *select*(2), and *epoll*(7). When events are available, the file descriptor indicates as readable. If the **O_NONBLOCK** flag is not enabled, then *poll*(2) (always) indicates the file as having a **POLLERR** condition, and *select*(2) indicates the file descriptor as both readable and writable.

RETURN VALUE

On success, **userfaultfd**() returns a new file descriptor that refers to the userfaultfd object. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL
An unsupported value was specified in *flags*.

EMFILE
The per-process limit on the number of open file descriptors has been reached

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOMEM
Insufficient kernel memory was available.

EPERM (since Linux 5.2)
The caller is not privileged (does not have the **CAP_SYS_PTRACE** capability in the initial user namespace), and */proc/sys/vm/unprivileged_userfaultfd* has the value 0.

STANDARDS

Linux.

HISTORY

Linux 4.3.

Support for hugetlbfs and shared memory areas and non-page-fault events was added in Linux 4.11

NOTES

The userfaultfd mechanism can be used as an alternative to traditional user-space paging techniques based on the use of the **SIGSEGV** signal and *mmap*(2). It can also be used to implement lazy restore for checkpoint/restore mechanisms, as well as post-copy migration to allow (nearly) uninterrupted execution when transferring virtual machines and Linux containers from one host to another.

BUGS

If the **UFFD_FEATURE_EVENT_FORK** is enabled and a system call from the *fork*(2) family is interrupted by a signal or failed, a stale userfaultfd descriptor might be created. In this case, a spurious **UFFD_EVENT_FORK** will be delivered to the userfaultfd monitor.

EXAMPLES

The program below demonstrates the use of the userfaultfd mechanism. The program creates two threads, one of which acts as the page-fault handler for the process, for the pages in a demand-page zero region created using *mmap*(2).

The program takes one command-line argument, which is the number of pages that will be created in a mapping whose page faults will be handled via userfaultfd. After creating a userfaultfd object, the program then creates an anonymous private mapping of the specified size and registers the address range of that mapping using the **UFFDIO_REGISTER** *ioctl*(2) operation. The program then creates a second thread that will perform the task of handling page faults.

The main thread then walks through the pages of the mapping fetching bytes from successive pages. Because the pages have not yet been accessed, the first access of a byte in each page will trigger a page-fault event on the userfaultfd file descriptor.

Each of the page-fault events is handled by the second thread, which sits in a loop processing input from the userfaultfd file descriptor. In each loop iteration, the second thread first calls *poll*(2) to check the state of the file descriptor, and then reads an event from the file descriptor. All such events should be **UFFD_EVENT_PAGEFAULT** events, which the thread handles by copying a page of data into the faulting region using the **UFFDIO_COPY** *ioctl*(2) operation.

The following is an example of what we see when running the program:

```
$ ./userfaultfd_demo 3
Address returned by mmap() = 0x7fd30106c000

fault_handler_thread():
    poll() returns: nready = 1; POLLIN = 1; POLLERR = 0
    UFFD_EVENT_PAGEFAULT event: flags = 0; address = 7fd30106c00f
        (uffdio_copy.copy returned 4096)
Read address 0x7fd30106c00f in main(): A
Read address 0x7fd30106c40f in main(): A

NAME

ustat − get filesystem statistics

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <unistd.h>    /* libc[45] */
#include <ustat.h>     /* glibc2 */

[[deprecated]] int ustat(dev_t dev, struct ustat *ubuf);
```

DESCRIPTION

ustat() returns information about a mounted filesystem. *dev* is a device number identifying a device containing a mounted filesystem. *ubuf* is a pointer to a *ustat* structure that contains the following members:

```
daddr_t f_tfree;      /* Total free blocks */
ino_t   f_tinode;     /* Number of free inodes */
char    f_fname[6];   /* Filsys name */
char    f_fpack[6];   /* Filsys pack name */
```

The last two fields, *f_fname* and *f_fpack*, are not implemented and will always be filled with null bytes ('\0').

RETURN VALUE

On success, zero is returned and the *ustat* structure pointed to by *ubuf* will be filled in. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT
: *ubuf* points outside of your accessible address space.

EINVAL
: *dev* does not refer to a device containing a mounted filesystem.

ENOSYS
: The mounted filesystem referenced by *dev* does not support this operation, or any version of Linux before Linux 1.3.16.

STANDARDS

None.

HISTORY

SVr4. Removed in glibc 2.28.

ustat() is deprecated and has been provided only for compatibility. All new programs should use *statfs*(2) instead.

HP-UX notes

The HP-UX version of the *ustat* structure has an additional field, *f_blksize*, that is unknown elsewhere. HP-UX warns: For some filesystems, the number of free inodes does not change. Such filesystems will return −1 in the field *f_tinode*. For some filesystems, inodes are dynamically allocated. Such filesystems will return the current number of free inodes.

SEE ALSO

stat(2), *statfs*(2)

NAME

utime, utimes − change file last access and modification times

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <utime.h>

int utime(const char *filename,
          const struct utimbuf *_Nullable times);

#include <sys/time.h>

int utimes(const char *filename,
           const struct timeval times[_Nullable 2]);
```

DESCRIPTION

Note: modern applications may prefer to use the interfaces described in *utimensat*(2).

The **utime**() system call changes the access and modification times of the inode specified by *filename* to the *actime* and *modtime* fields of *times* respectively. The status change time (ctime) will be set to the current time, even if the other time stamps don't actually change.

If *times* is NULL, then the access and modification times of the file are set to the current time.

Changing timestamps is permitted when: either the process has appropriate privileges, or the effective user ID equals the user ID of the file, or *times* is NULL and the process has write permission for the file.

The *utimbuf* structure is:

```
struct utimbuf {
    time_t actime;       /* access time */
    time_t modtime;      /* modification time */
};
```

The **utime**() system call allows specification of timestamps with a resolution of 1 second.

The **utimes**() system call is similar, but the *times* argument refers to an array rather than a structure. The elements of this array are *timeval* structures, which allow a precision of 1 microsecond for specifying timestamps. The *timeval* structure is:

```
struct timeval {
    long tv_sec;        /* seconds */
    long tv_usec;       /* microseconds */
};
```

times[0] specifies the new access time, and *times[1]* specifies the new modification time. If *times* is NULL, then analogously to **utime**(), the access and modification times of the file are set to the current time.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EACCES
: Search permission is denied for one of the directories in the path prefix of *path* (see also *path_resolution*(7)).

EACCES
: *times* is NULL, the caller's effective user ID does not match the owner of the file, the caller does not have write access to the file, and the caller is not privileged (Linux: does not have either the **CAP_DAC_OVERRIDE** or the **CAP_FOWNER** capability).

ENOENT
: *filename* does not exist.

EPERM
: *times* is not NULL, the caller's effective UID does not match the owner of the file, and the caller is not privileged (Linux: does not have the **CAP_FOWNER** capability).

EROFS
path resides on a read-only filesystem.

STANDARDS
POSIX.1-2008.

HISTORY
utime()
SVr4, POSIX.1-2001. POSIX.1-2008 marks it as obsolete.

utimes()
4.3BSD, POSIX.1-2001.

NOTES
Linux does not allow changing the timestamps on an immutable file, or setting the timestamps to something other than the current time on an append-only file.

NAME

utimensat, futimens − change file timestamps with nanosecond precision

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <fcntl.h>          /* Definition of AT_* constants */
#include <sys/stat.h>

int utimensat(int dirfd, const char *pathname,
              const struct timespec times[_Nullable 2], int flags);
int futimens(int fd, const struct timespec times[_Nullable 2]);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

utimensat():
  Since glibc 2.10:
    _POSIX_C_SOURCE >= 200809L
  Before glibc 2.10:
    _ATFILE_SOURCE

futimens():
  Since glibc 2.10:
    _POSIX_C_SOURCE >= 200809L
  Before glibc 2.10:
    _GNU_SOURCE

DESCRIPTION

utimensat() and **futimens**() update the timestamps of a file with nanosecond precision. This contrasts with the historical *utime*(2) and *utimes*(2), which permit only second and microsecond precision, respectively, when setting file timestamps.

With **utimensat**() the file is specified via the pathname given in *pathname*. With **futimens**() the file whose timestamps are to be updated is specified via an open file descriptor, *fd*.

For both calls, the new file timestamps are specified in the array *times*: *times[0]* specifies the new "last access time" (*atime*); *times[1]* specifies the new "last modification time" (*mtime*). Each of the elements of *times* specifies a time as the number of seconds and nanoseconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC). This information is conveyed in a *timespec*(3) structure.

Updated file timestamps are set to the greatest value supported by the filesystem that is not greater than the specified time.

If the *tv_nsec* field of one of the *timespec* structures has the special value **UTIME_NOW**, then the corresponding file timestamp is set to the current time. If the *tv_nsec* field of one of the *timespec* structures has the special value **UTIME_OMIT**, then the corresponding file timestamp is left unchanged. In both of these cases, the value of the corresponding *tv_sec* field is ignored.

If *times* is NULL, then both timestamps are set to the current time.

The status change time (ctime) will be set to the current time, even if the other time stamps don't actually change.

Permissions requirements

To set both file timestamps to the current time (i.e., *times* is NULL, or both *tv_nsec* fields specify **UTIME_NOW**), either:

- the caller must have write access to the file;
- the caller's effective user ID must match the owner of the file; or
- the caller must have appropriate privileges.

To make any change other than setting both timestamps to the current time (i.e., *times* is not NULL, and neither *tv_nsec* field is **UTIME_NOW** and neither *tv_nsec* field is **UTIME_OMIT**), either condition 2 or 3 above must apply.

If both *tv_nsec* fields are specified as **UTIME_OMIT**, then no file ownership or permission checks are performed, and the file timestamps are not modified, but other error conditions may still be detected.

utimensat() specifics

If *pathname* is relative, then by default it is interpreted relative to the directory referred to by the open file descriptor, *dirfd* (rather than relative to the current working directory of the calling process, as is done by *utimes*(2) for a relative pathname). See *openat*(2) for an explanation of why this can be useful.

If *pathname* is relative and *dirfd* is the special value **AT_FDCWD**, then *pathname* is interpreted relative to the current working directory of the calling process (like *utimes*(2)).

If *pathname* is absolute, then *dirfd* is ignored.

The *flags* argument is a bit mask created by ORing together zero or more of the following values defined in <*fcntl.h*>:

AT_EMPTY_PATH (since Linux 5.8)
: If *pathname* is an empty string, operate on the file referred to by *dirfd* (which may have been obtained using the *open*(2) **O_PATH** flag). In this case, *dirfd* can refer to any type of file, not just a directory. If *dirfd* is **AT_FDCWD**, the call operates on the current working directory. This flag is Linux-specific; define **_GNU_SOURCE** to obtain its definition.

AT_SYMLINK_NOFOLLOW
: If *pathname* specifies a symbolic link, then update the timestamps of the link, rather than the file to which it refers.

RETURN VALUE

On success, **utimensat**() and **futimens**() return 0. On error, −1 is returned and *errno* is set to indicate the error.

ERRORS

EACCES
: *times* is NULL, or both *tv_nsec* values are **UTIME_NOW**, and the effective user ID of the caller does not match the owner of the file, the caller does not have write access to the file, and the caller is not privileged (Linux: does not have either the **CAP_FOWNER** or the **CAP_DAC_OVERRIDE** capability).

EBADF
: (**futimens**()) *fd* is not a valid file descriptor.

EBADF
: (**utimensat**()) *pathname* is relative but *dirfd* is neither **AT_FDCWD** nor a valid file descriptor.

EFAULT
: *times* pointed to an invalid address; or, *dirfd* was **AT_FDCWD**, and *pathname* is NULL or an invalid address.

EINVAL
: Invalid value in *flags*.

EINVAL
: Invalid value in one of the *tv_nsec* fields (value outside range [0, 999,999,999], and not **UTIME_NOW** or **UTIME_OMIT**); or an invalid value in one of the *tv_sec* fields.

EINVAL
: *pathname* is NULL, *dirfd* is not **AT_FDCWD**, and *flags* contains **AT_SYMLINK_NOFOLLOW**.

ELOOP
: (**utimensat**()) Too many symbolic links were encountered in resolving *pathname*.

ENAMETOOLONG
: (**utimensat**()) *pathname* is too long.

ENOENT
: (**utimensat**()) A component of *pathname* does not refer to an existing directory or file, or *pathname* is an empty string.

ENOTDIR
: (**utimensat**()) *pathname* is a relative pathname, but *dirfd* is neither **AT_FDCWD** nor a file descriptor referring to a directory; or, one of the prefix components of *pathname* is not a

directory.

EPERM
The caller attempted to change one or both timestamps to a value other than the current time, or to change one of the timestamps to the current time while leaving the other timestamp unchanged, (i.e., *times* is not NULL, neither *tv_nsec* field is **UTIME_NOW**, and neither *tv_nsec* field is **UTIME_OMIT**) and either:

- the caller's effective user ID does not match the owner of file, and the caller is not privileged (Linux: does not have the **CAP_FOWNER** capability); or,
- the file is marked append-only or immutable (see *chattr*(1)).

EROFS
The file is on a read-only filesystem.

ESRCH
(**utimensat**()) Search permission is denied for one of the prefix components of *pathname*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
utimensat(), **futimens**()	Thread safety	MT-Safe

VERSIONS

C library/kernel ABI differences

On Linux, **futimens**() is a library function implemented on top of the **utimensat**() system call. To support this, the Linux **utimensat**() system call implements a nonstandard feature: if *pathname* is NULL, then the call modifies the timestamps of the file referred to by the file descriptor *dirfd* (which may refer to any type of file). Using this feature, the call *futimens(fd, times)* is implemented as:

```
utimensat(fd, NULL, times, 0);
```

Note, however, that the glibc wrapper for **utimensat**() disallows passing NULL as the value for *pathname*: the wrapper function returns the error **EINVAL** in this case.

STANDARDS

POSIX.1-2008.

VERSIONS

utimensat()
Linux 2.6.22, glibc 2.6. POSIX.1-2008.

futimens()
glibc 2.6. POSIX.1-2008.

NOTES

utimensat() obsoletes *futimesat*(2).

On Linux, timestamps cannot be changed for a file marked immutable, and the only change permitted for files marked append-only is to set the timestamps to the current time. (This is consistent with the historical behavior of *utime*(2) and *utimes*(2) on Linux.)

If both *tv_nsec* fields are specified as **UTIME_OMIT**, then the Linux implementation of **utimensat**() succeeds even if the file referred to by *dirfd* and *pathname* does not exist.

BUGS

Several bugs afflict **utimensat**() and **futimens**() before Linux 2.6.26. These bugs are either nonconformances with the POSIX.1 draft specification or inconsistencies with historical Linux behavior.

- POSIX.1 specifies that if one of the *tv_nsec* fields has the value **UTIME_NOW** or **UTIME_OMIT**, then the value of the corresponding *tv_sec* field should be ignored. Instead, the value of the *tv_sec* field is required to be 0 (or the error **EINVAL** results).
- Various bugs mean that for the purposes of permission checking, the case where both *tv_nsec* fields are set to **UTIME_NOW** isn't always treated the same as specifying *times* as NULL, and the case where one *tv_nsec* value is **UTIME_NOW** and the other is **UTIME_OMIT** isn't treated the same as specifying *times* as a pointer to an array of structures containing arbitrary time values. As a result, in some cases: a) file timestamps can be updated by a process that shouldn't have permission

to perform updates; b) file timestamps can't be updated by a process that should have permission to perform updates; and c) the wrong *errno* value is returned in case of an error.

- POSIX.1 says that a process that has *write access to the file* can make a call with *times* as NULL, or with *times* pointing to an array of structures in which both *tv_nsec* fields are **UTIME_NOW**, in order to update both timestamps to the current time. However, **futimens**() instead checks whether the *access mode of the file descriptor allows writing*.

NAME

vfork − create a child process and block parent

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

pid_t vfork(void);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

vfork():
  Since glibc 2.12:
    (_XOPEN_SOURCE >= 500) && ! (_POSIX_C_SOURCE >= 200809L)
      || /* Since glibc 2.19: */ _DEFAULT_SOURCE
      || /* glibc <= 2.19: */ _BSD_SOURCE
  Before glibc 2.12:
    _BSD_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

Standard description

(From POSIX.1) The **vfork**() function has the same effect as *fork*(2), except that the behavior is undefined if the process created by **vfork**() either modifies any data other than a variable of type *pid_t* used to store the return value from **vfork**(), or returns from the function in which **vfork**() was called, or calls any other function before successfully calling *_exit*(2) or one of the *exec*(3) family of functions.

Linux description

vfork(), just like *fork*(2), creates a child process of the calling process. For details and return value and errors, see *fork*(2).

vfork() is a special case of *clone*(2). It is used to create new processes without copying the page tables of the parent process. It may be useful in performance-sensitive applications where a child is created which then immediately issues an *execve*(2).

vfork() differs from *fork*(2) in that the calling thread is suspended until the child terminates (either normally, by calling *_exit*(2), or abnormally, after delivery of a fatal signal), or it makes a call to *execve*(2). Until that point, the child shares all memory with its parent, including the stack. The child must not return from the current function or call *exit*(3) (which would have the effect of calling exit handlers established by the parent process and flushing the parent's *stdio*(3) buffers), but may call *_exit*(2).

As with *fork*(2), the child process created by **vfork**() inherits copies of various of the caller's process attributes (e.g., file descriptors, signal dispositions, and current working directory); the **vfork**() call differs only in the treatment of the virtual address space, as described above.

Signals sent to the parent arrive after the child releases the parent's memory (i.e., after the child terminates or calls *execve*(2)).

Historic description

Under Linux, *fork*(2) is implemented using copy-on-write pages, so the only penalty incurred by *fork*(2) is the time and memory required to duplicate the parent's page tables, and to create a unique task structure for the child. However, in the bad old days a *fork*(2) would require making a complete copy of the caller's data space, often needlessly, since usually immediately afterward an *exec*(3) is done. Thus, for greater efficiency, BSD introduced the **vfork**() system call, which did not fully copy the address space of the parent process, but borrowed the parent's memory and thread of control until a call to *execve*(2) or an exit occurred. The parent process was suspended while the child was using its resources. The use of **vfork**() was tricky: for example, not modifying data in the parent process depended on knowing which variables were held in a register.

VERSIONS

The requirements put on **vfork**() by the standards are weaker than those put on *fork*(2), so an implementation where the two are synonymous is compliant. In particular, the programmer cannot rely on the parent remaining blocked until the child either terminates or calls *execve*(2), and cannot rely on any specific behavior with respect to shared memory.

Some consider the semantics of **vfork**() to be an architectural blemish, and the 4.2BSD man page

stated: "This system call will be eliminated when proper system sharing mechanisms are implemented. Users should not depend on the memory sharing semantics of *vfork* as it will, in that case, be made synonymous to *fork*." However, even though modern memory management hardware has decreased the performance difference between *fork*(2) and **vfork**(), there are various reasons why Linux and other systems have retained **vfork**():

- Some performance-critical applications require the small performance advantage conferred by **vfork**().
- **vfork**() can be implemented on systems that lack a memory-management unit (MMU), but *fork*(2) can't be implemented on such systems. (POSIX.1-2008 removed **vfork**() from the standard; the POSIX rationale for the *posix_spawn*(3) function notes that that function, which provides functionality equivalent to *fork*(2)+*exec*(3), is designed to be implementable on systems that lack an MMU.)
- On systems where memory is constrained, **vfork**() avoids the need to temporarily commit memory (see the description of */proc/sys/vm/overcommit_memory* in *proc*(5)) in order to execute a new program. (This can be especially beneficial where a large parent process wishes to execute a small helper program in a child process.) By contrast, using *fork*(2) in this scenario requires either committing an amount of memory equal to the size of the parent process (if strict overcommitting is in force) or overcommitting memory with the risk that a process is terminated by the out-of-memory (OOM) killer.

Linux notes

Fork handlers established using *pthread_atfork*(3) are not called when a multithreaded program employing the NPTL threading library calls **vfork**(). Fork handlers are called in this case in a program using the LinuxThreads threading library. (See *pthreads*(7) for a description of Linux threading libraries.)

A call to **vfork**() is equivalent to calling *clone*(2) with *flags* specified as:

```
CLONE_VM | CLONE_VFORK | SIGCHLD
```

STANDARDS

None.

HISTORY

4.3BSD; POSIX.1-2001 (but marked OBSOLETE). POSIX.1-2008 removes the specification of **vfork**().

The **vfork**() system call appeared in 3.0BSD. In 4.4BSD it was made synonymous to *fork*(2) but NetBSD introduced it again; see . In Linux, it has been equivalent to *fork*(2) until Linux 2.2.0-pre6 or so. Since Linux 2.2.0-pre9 (on i386, somewhat later on other architectures) it is an independent system call. Support was added in glibc 2.0.112.

CAVEATS

The child process should take care not to modify the memory in unintended ways, since such changes will be seen by the parent process once the child terminates or executes another program. In this regard, signal handlers can be especially problematic: if a signal handler that is invoked in the child of **vfork**() changes memory, those changes may result in an inconsistent process state from the perspective of the parent process (e.g., memory changes would be visible in the parent, but changes to the state of open file descriptors would not be visible).

When **vfork**() is called in a multithreaded process, only the calling thread is suspended until the child terminates or executes a new program. This means that the child is sharing an address space with other running code. This can be dangerous if another thread in the parent process changes credentials (using *setuid*(2) or similar), since there are now two processes with different privilege levels running in the same address space. As an example of the dangers, suppose that a multithreaded program running as root creates a child using **vfork**(). After the **vfork**(), a thread in the parent process drops the process to an unprivileged user in order to run some untrusted code (e.g., perhaps via plug-in opened with *dlopen*(3)). In this case, attacks are possible where the parent process uses *mmap*(2) to map in code that will be executed by the privileged child process.

BUGS

Details of the signal handling are obscure and differ between systems. The BSD man page states: "To avoid a possible deadlock situation, processes that are children in the middle of a **vfork**() are never sent **SIGTTOU** or **SIGTTIN** signals; rather, output or *ioctl*s are allowed and input attempts result in an

end-of-file indication."

NAME

vhangup − virtually hangup the current terminal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int vhangup(void);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

vhangup():
Since glibc 2.21:
_DEFAULT_SOURCE
In glibc 2.19 and 2.20:
_DEFAULT_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)
Up to and including glibc 2.19:
_BSD_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)

DESCRIPTION

vhangup() simulates a hangup on the current terminal. This call arranges for other users to have a "clean" terminal at login time.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EPERM
The calling process has insufficient privilege to call **vhangup**(); the **CAP_SYS_TTY_CONFIG** capability is required.

STANDARDS

Linux.

init(1), *capabilities*(7)

NAME

vm86old, vm86 − enter virtual 8086 mode

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/vm86.h>

int vm86old(struct vm86_struct ****info*);**
int vm86(unsigned long *fn***, struct vm86plus_struct ****v86***);**

DESCRIPTION

The system call **vm86**() was introduced in Linux 0.97p2. In Linux 2.1.15 and 2.0.28, it was renamed to **vm86old**(), and a new **vm86**() was introduced. The definition of *struct vm86_struct* was changed in 1.1.8 and 1.1.9.

These calls cause the process to enter VM86 mode (virtual-8086 in Intel literature), and are used by **dosemu**.

VM86 mode is an emulation of real mode within a protected mode task.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT
: This return value is specific to i386 and indicates a problem with getting user-space data.

ENOSYS
: This return value indicates the call is not implemented on the present architecture.

EPERM
: Saved kernel stack exists. (This is a kernel sanity check; the saved stack should exist only within vm86 mode itself.)

STANDARDS

Linux on 32-bit Intel processors.

NAME

vmsplice − splice user pages to/from a pipe

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <fcntl.h>

ssize_t vmsplice(int fd, const struct iovec *iov,
                 size_t nr_segs, unsigned int flags);
```

DESCRIPTION

If *fd* is opened for writing, the **vmsplice**() system call maps *nr_segs* ranges of user memory described by *iov* into a pipe. If *fd* is opened for reading, the **vmsplice**() system call fills *nr_segs* ranges of user memory described by *iov* from a pipe. The file descriptor *fd* must refer to a pipe.

The pointer *iov* points to an array of *iovec* structures as described in *iovec*(3type).

The *flags* argument is a bit mask that is composed by ORing together zero or more of the following values:

SPLICE_F_MOVE
: Unused for **vmsplice**(); see *splice*(2).

SPLICE_F_NONBLOCK
: Do not block on I/O; see *splice*(2) for further details.

SPLICE_F_MORE
: Currently has no effect for **vmsplice**(), but may be implemented in the future; see *splice*(2).

SPLICE_F_GIFT
: The user pages are a gift to the kernel. The application may not modify this memory ever, otherwise the page cache and on-disk data may differ. Gifting pages to the kernel means that a subsequent *splice*(2) **SPLICE_F_MOVE** can successfully move the pages; if this flag is not specified, then a subsequent *splice*(2) **SPLICE_F_MOVE** must copy the pages. Data must also be properly page aligned, both in memory and length.

RETURN VALUE

Upon successful completion, **vmsplice**() returns the number of bytes transferred to the pipe. On error, **vmsplice**() returns −1 and *errno* is set to indicate the error.

ERRORS

EAGAIN
: **SPLICE_F_NONBLOCK** was specified in *flags*, and the operation would block.

EBADF
: *fd* either not valid, or doesn't refer to a pipe.

EINVAL
: *nr_segs* is greater than **IOV_MAX**; or memory not aligned if **SPLICE_F_GIFT** set.

ENOMEM
: Out of memory.

STANDARDS

Linux.

HISTORY

Linux 2.6.17, glibc 2.5.

NOTES

vmsplice() follows the other vectorized read/write type functions when it comes to limitations on the number of segments being passed in. This limit is **IOV_MAX** as defined in <*limits.h*>. Currently, this limit is 1024.

vmsplice() really supports true splicing only from user memory to a pipe. In the opposite direction, it actually just copies the data to user space. But this makes the interface nice and symmetric and enables people to build on **vmsplice**() with room for future improvement in performance.

splice(2), *tee*(2), *pipe*(7)

NAME

wait, waitpid, waitid − wait for process to change state

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/wait.h>

pid_t wait(int *_Nullable wstatus);
pid_t waitpid(pid_t pid, int *_Nullable wstatus, int options);

int waitid(idtype_t idtype, id_t id, siginfo_t *infop, int options);
                /* This is the glibc and POSIX interface; see
                   NOTES for information on the raw system call. */
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

waitid():
Since glibc 2.26:
_XOPEN_SOURCE >= 500 || _POSIX_C_SOURCE >= 200809L
glibc 2.25 and earlier:
_XOPEN_SOURCE
|| /* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L
|| /* glibc <= 2.19: */ _BSD_SOURCE

DESCRIPTION

All of these system calls are used to wait for state changes in a child of the calling process, and obtain information about the child whose state has changed. A state change is considered to be: the child terminated; the child was stopped by a signal; or the child was resumed by a signal. In the case of a terminated child, performing a wait allows the system to release the resources associated with the child; if a wait is not performed, then the terminated child remains in a "zombie" state (see NOTES below).

If a child has already changed state, then these calls return immediately. Otherwise, they block until either a child changes state or a signal handler interrupts the call (assuming that system calls are not automatically restarted using the **SA_RESTART** flag of *sigaction*(2)). In the remainder of this page, a child whose state has changed and which has not yet been waited upon by one of these system calls is termed *waitable*.

wait() and waitpid()

The **wait**() system call suspends execution of the calling thread until one of its children terminates. The call *wait(&wstatus)* is equivalent to:

```
waitpid(−1, &wstatus, 0);
```

The **waitpid**() system call suspends execution of the calling thread until a child specified by *pid* argument has changed state. By default, **waitpid**() waits only for terminated children, but this behavior is modifiable via the *options* argument, as described below.

The value of *pid* can be:

< **−1** meaning wait for any child process whose process group ID is equal to the absolute value of *pid*.

−1 meaning wait for any child process.

0 meaning wait for any child process whose process group ID is equal to that of the calling process at the time of the call to **waitpid**().

> **0** meaning wait for the child whose process ID is equal to the value of *pid*.

The value of *options* is an OR of zero or more of the following constants:

WNOHANG
return immediately if no child has exited.

WUNTRACED
also return if a child has stopped (but not traced via *ptrace*(2)). Status for *traced* children which have stopped is provided even if this option is not specified.

WCONTINUED (since Linux 2.6.10)
also return if a stopped child has been resumed by delivery of **SIGCONT**.

(For Linux-only options, see below.)

If *wstatus* is not NULL, **wait**() and **waitpid**() store status information in the *int* to which it points. This integer can be inspected with the following macros (which take the integer itself as an argument, not a pointer to it, as is done in **wait**() and *waitpid*()!):

WIFEXITED(*wstatus***)**
returns true if the child terminated normally, that is, by calling *exit*(3) or *_exit*(2), or by returning from main().

WEXITSTATUS(*wstatus***)**
returns the exit status of the child. This consists of the least significant 8 bits of the *status* argument that the child specified in a call to *exit*(3) or *_exit*(2) or as the argument for a return statement in main(). This macro should be employed only if **WIFEXITED** returned true.

WIFSIGNALED(*wstatus***)**
returns true if the child process was terminated by a signal.

WTERMSIG(*wstatus***)**
returns the number of the signal that caused the child process to terminate. This macro should be employed only if **WIFSIGNALED** returned true.

WCOREDUMP(*wstatus***)**
returns true if the child produced a core dump (see *core*(5)). This macro should be employed only if **WIFSIGNALED** returned true.

This macro is not specified in POSIX.1-2001 and is not available on some UNIX implementations (e.g., AIX, SunOS). Therefore, enclose its use inside *#ifdef WCOREDUMP ... #endif*.

WIFSTOPPED(*wstatus***)**
returns true if the child process was stopped by delivery of a signal; this is possible only if the call was done using **WUNTRACED** or when the child is being traced (see *ptrace*(2)).

WSTOPSIG(*wstatus***)**
returns the number of the signal which caused the child to stop. This macro should be employed only if **WIFSTOPPED** returned true.

WIFCONTINUED(*wstatus***)**
(since Linux 2.6.10) returns true if the child process was resumed by delivery of **SIGCONT**.

waitid()
The **waitid**() system call (available since Linux 2.6.9) provides more precise control over which child state changes to wait for.

The *idtype* and *id* arguments select the child(ren) to wait for, as follows:

idtype == **P_PID**
Wait for the child whose process ID matches *id*.

idtype == **P_PIDFD** (since Linux 5.4)
Wait for the child referred to by the PID file descriptor specified in *id*. (See *pidfd_open*(2) for further information on PID file descriptors.)

idtype == **P_PGID**
Wait for any child whose process group ID matches *id*. Since Linux 5.4, if *id* is zero, then wait for any child that is in the same process group as the caller's process group at the time of the call.

idtype == **P_ALL**
Wait for any child; *id* is ignored.

The child state changes to wait for are specified by ORing one or more of the following flags in *options*:

WEXITED
Wait for children that have terminated.

WSTOPPED
Wait for children that have been stopped by delivery of a signal.

WCONTINUED
Wait for (previously stopped) children that have been resumed by delivery of **SIGCONT**.

The following flags may additionally be ORed in *options*:

WNOHANG
As for **waitpid**().

WNOWAIT
Leave the child in a waitable state; a later wait call can be used to again retrieve the child status information.

Upon successful return, **waitid**() fills in the following fields of the *siginfo_t* structure pointed to by *infop*:

si_pid The process ID of the child.

si_uid The real user ID of the child. (This field is not set on most other implementations.)

si_signo
Always set to **SIGCHLD**.

si_status
Either the exit status of the child, as given to *_exit*(2) (or *exit*(3)), or the signal that caused the child to terminate, stop, or continue. The *si_code* field can be used to determine how to interpret this field.

si_code Set to one of: **CLD_EXITED** (child called *_exit*(2)); **CLD_KILLED** (child killed by signal); **CLD_DUMPED** (child killed by signal, and dumped core); **CLD_STOPPED** (child stopped by signal); **CLD_TRAPPED** (traced child has trapped); or **CLD_CONTINUED** (child continued by **SIGCONT**).

If **WNOHANG** was specified in *options* and there were no children in a waitable state, then **waitid**() returns 0 immediately and the state of the *siginfo_t* structure pointed to by *infop* depends on the implementation. To (portably) distinguish this case from that where a child was in a waitable state, zero out the *si_pid* field before the call and check for a nonzero value in this field after the call returns.

POSIX.1-2008 Technical Corrigendum 1 (2013) adds the requirement that when **WNOHANG** is specified in *options* and there were no children in a waitable state, then **waitid**() should zero out the *si_pid* and *si_signo* fields of the structure. On Linux and other implementations that adhere to this requirement, it is not necessary to zero out the *si_pid* field before calling **waitid**(). However, not all implementations follow the POSIX.1 specification on this point.

RETURN VALUE

wait(): on success, returns the process ID of the terminated child; on failure, −1 is returned.

waitpid(): on success, returns the process ID of the child whose state has changed; if **WNOHANG** was specified and one or more child(ren) specified by *pid* exist, but have not yet changed state, then 0 is returned. On failure, −1 is returned.

waitid(): returns 0 on success or if **WNOHANG** was specified and no child(ren) specified by *id* has yet changed state; on failure, −1 is returned.

On failure, each of these calls sets *errno* to indicate the error.

ERRORS

EAGAIN
The PID file descriptor specified in *id* is nonblocking and the process that it refers to has not terminated.

ECHILD
(for *wait*()) The calling process does not have any unwaited-for children.

ECHILD
(for **waitpid**() or *waitid*()) The process specified by *pid* (**waitpid**()) or *idtype* and *id* (**waitid**()) does not exist or is not a child of the calling process. (This can happen for one's own child if the action for **SIGCHLD** is set to **SIG_IGN**. See also the *Linux Notes* section

about threads.)

EINTR
WNOHANG was not set and an unblocked signal or a **SIGCHLD** was caught; see *signal*(7).

EINVAL
The *options* argument was invalid.

ESRCH
(for **wait**() or *waitpid*()) *pid* is equal to **INT_MIN**.

VERSIONS

C library/kernel differences

wait() is actually a library function that (in glibc) is implemented as a call to *wait4*(2).

On some architectures, there is no **waitpid**() system call; instead, this interface is implemented via a C library wrapper function that calls *wait4*(2).

The raw **waitid**() system call takes a fifth argument, of type *struct rusage* *. If this argument is non-NULL, then it is used to return resource usage information about the child, in the same manner as *wait4*(2). See *getrusage*(2) for details.

STANDARDS

POSIX.1-2008.

HISTORY

SVr4, 4.3BSD, POSIX.1-2001.

NOTES

A child that terminates, but has not been waited for becomes a "zombie". The kernel maintains a minimal set of information about the zombie process (PID, termination status, resource usage information) in order to allow the parent to later perform a wait to obtain information about the child. As long as a zombie is not removed from the system via a wait, it will consume a slot in the kernel process table, and if this table fills, it will not be possible to create further processes. If a parent process terminates, then its "zombie" children (if any) are adopted by *init*(1), (or by the nearest "subreaper" process as defined through the use of the *prctl*(2) **PR_SET_CHILD_SUBREAPER** operation); *init*(1) automatically performs a wait to remove the zombies.

POSIX.1-2001 specifies that if the disposition of **SIGCHLD** is set to **SIG_IGN** or the **SA_NOCLDWAIT** flag is set for **SIGCHLD** (see *sigaction*(2)), then children that terminate do not become zombies and a call to **wait**() or **waitpid**() will block until all children have terminated, and then fail with *errno* set to **ECHILD**. (The original POSIX standard left the behavior of setting **SIGCHLD** to **SIG_IGN** unspecified. Note that even though the default disposition of **SIGCHLD** is "ignore", explicitly setting the disposition to **SIG_IGN** results in different treatment of zombie process children.)

Linux 2.6 conforms to the POSIX requirements. However, Linux 2.4 (and earlier) does not: if a **wait**() or **waitpid**() call is made while **SIGCHLD** is being ignored, the call behaves just as though **SIGCHLD** were not being ignored, that is, the call blocks until the next child terminates and then returns the process ID and status of that child.

Linux notes

In the Linux kernel, a kernel-scheduled thread is not a distinct construct from a process. Instead, a thread is simply a process that is created using the Linux-unique *clone*(2) system call; other routines such as the portable *pthread_create*(3) call are implemented using *clone*(2). Before Linux 2.4, a thread was just a special case of a process, and as a consequence one thread could not wait on the children of another thread, even when the latter belongs to the same thread group. However, POSIX prescribes such functionality, and since Linux 2.4 a thread can, and by default will, wait on children of other threads in the same thread group.

The following Linux-specific *options* are for use with children created using *clone*(2); they can also, since Linux 4.7, be used with **waitid**():

__WCLONE
Wait for "clone" children only. If omitted, then wait for "non-clone" children only. (A "clone" child is one which delivers no signal, or a signal other than **SIGCHLD** to its parent upon termination.) This option is ignored if **__WALL** is also specified.

__WALL (since Linux 2.4)
Wait for all children, regardless of type ("clone" or "non-clone").

__WNOTHREAD (since Linux 2.4)
Do not wait for children of other threads in the same thread group. This was the default before Linux 2.4.

Since Linux 4.7, the **__WALL** flag is automatically implied if the child is being ptraced.

BUGS

According to POSIX.1-2008, an application calling **waitid**() must ensure that *infop* points to a *siginfo_t* structure (i.e., that it is a non-null pointer). On Linux, if *infop* is NULL, **waitid**() succeeds, and returns the process ID of the waited-for child. Applications should avoid relying on this inconsistent, nonstandard, and unnecessary feature.

EXAMPLES

The following program demonstrates the use of *fork*(2) and **waitpid**(). The program creates a child process. If no command-line argument is supplied to the program, then the child suspends its execution using *pause*(2), to allow the user to send signals to the child. Otherwise, if a command-line argument is supplied, then the child exits immediately, using the integer supplied on the command line as the exit status. The parent process executes a loop that monitors the child using **waitpid**(), and uses the W*() macros described above to analyze the wait status value.

The following shell session demonstrates the use of the program:

```
$ ./a.out &
Child PID is 32360
[1] 32359
$ kill -STOP 32360
stopped by signal 19
$ kill -CONT 32360
continued
$ kill -TERM 32360
killed by signal 15
[1]+  Done                    ./a.out
$
```

Program source

```
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/wait.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    int    wstatus;
    pid_t  cpid, w;

    cpid = fork();
    if (cpid == -1) {
        perror("fork");
        exit(EXIT_FAILURE);
    }

    if (cpid == 0) {            /* Code executed by child */
        printf("Child PID is %jd\n", (intmax_t) getpid());
        if (argc == 1)
            pause();                    /* Wait for signals */
        _exit(atoi(argv[1]));
```

```
        } else {                    /* Code executed by parent */
            do {
                w = waitpid(cpid, &wstatus, WUNTRACED | WCONTINUED);
                if (w == -1) {
                    perror("waitpid");
                    exit(EXIT_FAILURE);
                }

                if (WIFEXITED(wstatus)) {
                    printf("exited, status=%d\n", WEXITSTATUS(wstatus));
                } else if (WIFSIGNALED(wstatus)) {
                    printf("killed by signal %d\n", WTERMSIG(wstatus));
                } else if (WIFSTOPPED(wstatus)) {
                    printf("stopped by signal %d\n", WSTOPSIG(wstatus));
                } else if (WIFCONTINUED(wstatus)) {
                    printf("continued\n");
                }
            } while (!WIFEXITED(wstatus) && !WIFSIGNALED(wstatus));
            exit(EXIT_SUCCESS);
        }
    }
```

NAME

wait3, wait4 − wait for process to change state, BSD style

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/wait.h>

pid_t wait3(int *_Nullable wstatus, int options,
            struct rusage *_Nullable rusage);
pid_t wait4(pid_t pid, int *_Nullable wstatus, int options,
            struct rusage *_Nullable rusage);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

wait3():
Since glibc 2.26:
_DEFAULT_SOURCE
|| (_XOPEN_SOURCE >= 500 &&
! (_POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 600))
From glibc 2.19 to glibc 2.25:
_DEFAULT_SOURCE || _XOPEN_SOURCE >= 500
glibc 2.19 and earlier:
_BSD_SOURCE || _XOPEN_SOURCE >= 500

wait4():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

These functions are nonstandard; in new programs, the use of *waitpid*(2) or *waitid*(2) is preferable.

The **wait3**() and **wait4**() system calls are similar to *waitpid*(2), but additionally return resource usage information about the child in the structure pointed to by *rusage*.

Other than the use of the *rusage* argument, the following **wait3**() call:

```
wait3(wstatus, options, rusage);
```

is equivalent to:

```
waitpid(-1, wstatus, options);
```

Similarly, the following **wait4**() call:

```
wait4(pid, wstatus, options, rusage);
```

is equivalent to:

```
waitpid(pid, wstatus, options);
```

In other words, **wait3**() waits of any child, while **wait4**() can be used to select a specific child, or children, on which to wait. See *wait*(2) for further details.

If *rusage* is not NULL, the *struct rusage* to which it points will be filled with accounting information about the child. See *getrusage*(2) for details.

RETURN VALUE

As for *waitpid*(2).

ERRORS

As for *waitpid*(2).

STANDARDS

None.

HISTORY

4.3BSD.

SUSv1 included a specification of **wait3**(); SUSv2 included **wait3**(), but marked it LEGACY; SUSv3 removed it.

Including <*sys/time.h*> is not required these days, but increases portability. (Indeed, <*sys/resource.h*> defines the *rusage* structure with fields of type *struct timeval* defined in <*sys/time.h*>.)

C library/kernel differences

On Linux, **wait3**() is a library function implemented on top of the **wait4**() system call.

SEE ALSO

fork(2), *getrusage*(2), *sigaction*(2), *signal*(2), *wait*(2), *signal*(7)

NAME

write − write to a file descriptor

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

ssize_t write(int *fd***, const void** *buf***[.***count***], size_t** *count***);**

DESCRIPTION

write() writes up to *count* bytes from the buffer starting at *buf* to the file referred to by the file descriptor *fd*.

The number of bytes written may be less than *count* if, for example, there is insufficient space on the underlying physical medium, or the **RLIMIT_FSIZE** resource limit is encountered (see *setrlimit*(2)), or the call was interrupted by a signal handler after having written less than *count* bytes. (See also *pipe*(7).)

For a seekable file (i.e., one to which *lseek*(2) may be applied, for example, a regular file) writing takes place at the file offset, and the file offset is incremented by the number of bytes actually written. If the file was *open*(2)ed with **O_APPEND**, the file offset is first set to the end of the file before writing. The adjustment of the file offset and the write operation are performed as an atomic step.

POSIX requires that a *read*(2) that can be proved to occur after a **write**() has returned will return the new data. Note that not all filesystems are POSIX conforming.

According to POSIX.1, if *count* is greater than **SSIZE_MAX**, the result is implementation-defined; see NOTES for the upper limit on Linux.

RETURN VALUE

On success, the number of bytes written is returned. On error, −1 is returned, and *errno* is set to indicate the error.

Note that a successful **write**() may transfer fewer than *count* bytes. Such partial writes can occur for various reasons; for example, because there was insufficient space on the disk device to write all of the requested bytes, or because a blocked **write**() to a socket, pipe, or similar was interrupted by a signal handler after it had transferred some, but before it had transferred all of the requested bytes. In the event of a partial write, the caller can make another **write**() call to transfer the remaining bytes. The subsequent call will either transfer further bytes or may result in an error (e.g., if the disk is now full).

If *count* is zero and *fd* refers to a regular file, then **write**() may return a failure status if one of the errors below is detected. If no errors are detected, or error detection is not performed, 0 is returned without causing any other effect. If *count* is zero and *fd* refers to a file other than a regular file, the results are not specified.

ERRORS

EAGAIN
: The file descriptor *fd* refers to a file other than a socket and has been marked nonblocking (**O_NONBLOCK**), and the write would block. See *open*(2) for further details on the **O_NONBLOCK** flag.

EAGAIN or **EWOULDBLOCK**
: The file descriptor *fd* refers to a socket and has been marked nonblocking (**O_NONBLOCK**), and the write would block. POSIX.1-2001 allows either error to be returned for this case, and does not require these constants to have the same value, so a portable application should check for both possibilities.

EBADF
: *fd* is not a valid file descriptor or is not open for writing.

EDESTADDRREQ
: *fd* refers to a datagram socket for which a peer address has not been set using *connect*(2).

EDQUOT
: The user's quota of disk blocks on the filesystem containing the file referred to by *fd* has been exhausted.

EFAULT
buf is outside your accessible address space.

EFBIG
An attempt was made to write a file that exceeds the implementation-defined maximum file size or the process's file size limit, or to write at a position past the maximum allowed offset.

EINTR
The call was interrupted by a signal before any data was written; see *signal*(7).

EINVAL
fd is attached to an object which is unsuitable for writing; or the file was opened with the **O_DIRECT** flag, and either the address specified in *buf*, the value specified in *count*, or the file offset is not suitably aligned.

EIO A low-level I/O error occurred while modifying the inode. This error may relate to the write-back of data written by an earlier **write**(), which may have been issued to a different file descriptor on the same file. Since Linux 4.13, errors from write-back come with a promise that they *may* be reported by subsequent. **write**() requests, and *will* be reported by a subsequent *fsync*(2) (whether or not they were also reported by *write*())An alternate cause of **EIO** on networked filesystems is when an advisory lock had been taken out on the file descriptor and this lock has been lost. See the *Lost locks* section of *fcntl*(2) for further details.

ENOSPC
The device containing the file referred to by *fd* has no room for the data.

EPERM
The operation was prevented by a file seal; see *fcntl*(2).

EPIPE *fd* is connected to a pipe or socket whose reading end is closed. When this happens the writing process will also receive a **SIGPIPE** signal. (Thus, the write return value is seen only if the program catches, blocks or ignores this signal.)

Other errors may occur, depending on the object connected to *fd*.

STANDARDS
POSIX.1-2008.

HISTORY
SVr4, 4.3BSD, POSIX.1-2001.

Under SVr4 a write may be interrupted and return **EINTR** at any point, not just before any data is written.

NOTES
A successful return from **write**() does not make any guarantee that data has been committed to disk. On some filesystems, including NFS, it does not even guarantee that space has successfully been reserved for the data. In this case, some errors might be delayed until a future **write**(), *fsync*(2), or even *close*(2). The only way to be sure is to call *fsync*(2) after you are done writing all your data.

If a **write**() is interrupted by a signal handler before any bytes are written, then the call fails with the error **EINTR**; if it is interrupted after at least one byte has been written, the call succeeds, and returns the number of bytes written.

On Linux, **write**() (and similar system calls) will transfer at most 0x7ffff000 (2,147,479,552) bytes, returning the number of bytes actually transferred. (This is true on both 32-bit and 64-bit systems.)

An error return value while performing **write**() using direct I/O does not mean the entire write has failed. Partial data may be written and the data at the file offset on which the **write**() was attempted should be considered inconsistent.

BUGS
According to POSIX.1-2008/SUSv4 Section XSI 2.9.7 ("Thread Interactions with Regular File Operations"):

> All of the following functions shall be atomic with respect to each other in the effects specified in POSIX.1-2008 when they operate on regular files or symbolic links: ...

Among the APIs subsequently listed are **write**() and *writev*(2). And among the effects that should be

atomic across threads (and processes) are updates of the file offset. However, before Linux 3.14, this was not the case: if two processes that share an open file description (see *open*(2)) perform a **write**() (or *writev*(2)) at the same time, then the I/O operations were not atomic with respect to updating the file offset, with the result that the blocks of data output by the two processes might (incorrectly) overlap. This problem was fixed in Linux 3.14.

NAME

open_how − how to open a pathname

LIBRARY

Linux kernel headers

SYNOPSIS

```
#include <linux/openat2.h>

struct open_how {
    u64  flags;    /* O_* flags */
    u64  mode;     /* Mode for O_{CREAT,TMPFILE} */
    u64  resolve;  /* RESOLVE_* flags */
    /* ... */
};
```

DESCRIPTION

Specifies how a pathname should be opened.

The fields are as follows:

flags This field specifies the file creation and file status flags to use when opening the file.

mode This field specifies the mode for the new file.

resolve This is a bit mask of flags that modify the way in which *all* components of a pathname will be resolved (see *path_resolution*(7) for background information).

VERSIONS

Extra fields may be appended to the structure, with a zero value in a new field resulting in the kernel behaving as though that extension field was not present. Therefore, a user *must* zero-fill this structure on initialization.

STANDARDS

Linux.

openat2(2)

NAME

intro − introduction to library functions

DESCRIPTION

Section 3 of the manual describes all library functions excluding the library functions (system call wrappers) described in Section 2, which implement system calls.

Many of the functions described in the section are part of the Standard C Library (*libc*). Some functions are part of other libraries (e.g., the math library, *libm*, or the real-time library, *librt*) in which case the manual page will indicate the linker option needed to link against the required library (e.g., *−lm* and *−lrt*, respectively, for the aforementioned libraries).

In some cases, the programmer must define a feature test macro in order to obtain the declaration of a function from the header file specified in the man page SYNOPSIS section. (Where required, these *feature test macros* must be defined before including *any* header files.) In such cases, the required macro is described in the man page. For further information on feature test macros, see *feature_test_macros*(7).

Subsections

Section 3 of this manual is organized into subsections that reflect the complex structure of the standard C library and its many implementations:

- 3const
- 3head
- 3type

This difficult history frequently makes it a poor example to follow in design, implementation, and presentation.

Ideally, a library for the C language is designed such that each header file presents the interface to a coherent software module. It provides a small number of function declarations and exposes only data types and constants that are required for use of those functions. Together, these are termed an API or *application program interface*. Types and constants to be shared among multiple APIs should be placed in header files that declare no functions. This organization permits a C library module to be documented concisely with one header file per manual page. Such an approach improves the readability and accessibility of library documentation, and thereby the usability of the software.

STANDARDS

Certain terms and abbreviations are used to indicate UNIX variants and standards to which calls in this section conform. See *standards*(7).

NOTES

Authors and copyright conditions

Look at the header of the manual page source for the author(s) and copyright conditions. Note that these can be different from page to page!

intro(2), *errno*(3), *capabilities*(7), *credentials*(7), *environ*(7), *feature_test_macros*(7), *libc*(7), *math_error*(7), *path_resolution*(7), *pthreads*(7), *signal*(7), *standards*(7), *system_data_types*(7)

NAME

a64l, l64a − convert between long and base-64

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

long a64l(const char *str64);
char *l64a(long value);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

a64l(), **l64a**():
_XOPEN_SOURCE >= 500
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE

DESCRIPTION

These functions provide a conversion between 32-bit long integers and little-endian base-64 ASCII strings (of length zero to six). If the string used as argument for **a64l**() has length greater than six, only the first six bytes are used. If the type *long* has more than 32 bits, then **l64a**() uses only the low order 32 bits of *value*, and **a64l**() sign-extends its 32-bit result.

The 64 digits in the base-64 system are:

'.'	represents a 0
'/'	represents a 1
0-9	represent 2-11
A-Z	represent 12-37
a-z	represent 38-63

So 123 = 59*64^0 + 1*64^1 = "v/".

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
l64a()	Thread safety	MT-Unsafe race:l64a
a64l()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

The value returned by **l64a**() may be a pointer to a static buffer, possibly overwritten by later calls.

The behavior of **l64a**() is undefined when *value* is negative. If *value* is zero, it returns an empty string.

These functions are broken before glibc 2.2.5 (puts most significant digit first).

This is not the encoding used by *uuencode*(1)

SEE ALSO

uuencode(1), *strtoul*(3)

NAME

abort − cause abnormal process termination

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

[[noreturn]] void abort(void);

DESCRIPTION

The **abort**() function first unblocks the **SIGABRT** signal, and then raises that signal for the calling process (as though *raise*(3) was called). This results in the abnormal termination of the process unless the **SIGABRT** signal is caught and the signal handler does not return (see *longjmp*(3)).

If the **SIGABRT** signal is ignored, or caught by a handler that returns, the **abort**() function will still terminate the process. It does this by restoring the default disposition for **SIGABRT** and then raising the signal for a second time.

As with other cases of abnormal termination the functions registered with *atexit*(3) and *on_exit*(3) are not called.

RETURN VALUE

The **abort**() function never returns.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
abort()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

SVr4, POSIX.1-2001, 4.3BSD, C89.

Up until glibc 2.26, if the **abort**() function caused process termination, all open streams were closed and flushed (as with *fclose*(3)). However, in some cases this could result in deadlocks and data corruption. Therefore, starting with glibc 2.27, **abort**() terminates the process without flushing streams. POSIX.1 permits either possible behavior, saying that **abort**() "may include an attempt to effect fclose() on all open streams".

SEE ALSO

gdb(1), *sigaction*(2), *assert*(3), *exit*(3), *longjmp*(3), *raise*(3)

NAME

abs, labs, llabs, imaxabs − compute the absolute value of an integer

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int abs(int j);
long labs(long j);
long long llabs(long long j);

#include <inttypes.h>

intmax_t imaxabs(intmax_t j);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

llabs():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **abs**() function computes the absolute value of the integer argument *j*. The **labs**(), **llabs**(), and **imaxabs**() functions compute the absolute value of the argument *j* of the appropriate integer type for the function.

RETURN VALUE

Returns the absolute value of the integer argument, of the appropriate integer type for the function.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
abs(), **labs**(), **llabs**(), **imaxabs**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99, SVr4, 4.3BSD.

C89 only includes the **abs**() and **labs**() functions; the functions **llabs**() and **imaxabs**() were added in C99.

NOTES

Trying to take the absolute value of the most negative integer is not defined.

The **llabs**() function is included since glibc 2.0. The **imaxabs**() function is included since glibc 2.1.1.

For **llabs**() to be declared, it may be necessary to define **_ISOC99_SOURCE** or **_ISOC9X_SOURCE** (depending on the version of glibc) before including any standard headers.

By default, GCC handles **abs**(), **labs**(), and (since GCC 3.0) **llabs**() and **imaxabs**() as built-in functions.

SEE ALSO

cabs(3), *ceil*(3), *fabs*(3), *floor*(3), *rint*(3)

NAME

acos, acosf, acosl − arc cosine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double acos(double x);
float acosf(float x);
long double acosl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

acosf(), **acosl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions calculate the arc cosine of *x*; that is the value whose cosine is *x*.

RETURN VALUE

On success, these functions return the arc cosine of *x* in radians; the return value is in the range [0, pi].

If *x* is a NaN, a NaN is returned.

If *x* is +1, +0 is returned.

If *x* is positive infinity or negative infinity, a domain error occurs, and a NaN is returned.

If *x* is outside the range [−1, 1], a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is outside the range [−1, 1]
errno is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
acos(), **acosf**(), **acosl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to C89, SVr4, 4.3BSD.

NAME

acosh, acoshf, acoshl − inverse hyperbolic cosine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double acosh(double x);
float acoshf(float x);
long double acoshl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

acosh():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

acoshf(), **acoshl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions calculate the inverse hyperbolic cosine of *x*; that is the value whose hyperbolic cosine is *x*.

RETURN VALUE

On success, these functions return the inverse hyperbolic cosine of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is +1, +0 is returned.

If *x* is positive infinity, positive infinity is returned.

If *x* is less than 1, a domain error occurs, and the functions return a NaN.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is less than 1
errno is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
acosh(), **acoshf**(), **acoshl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD.

NAME

addseverity − introduce new severity classes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <fmtmsg.h>

int addseverity(int *severity***, const char *****s***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

addseverity():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

This function allows the introduction of new severity classes which can be addressed by the *severity* argument of the *fmtmsg*(3) function. By default, that function knows only how to print messages for severity 0-4 (with strings (none), HALT, ERROR, WARNING, INFO). This call attaches the given string *s* to the given value *severity*. If *s* is NULL, the severity class with the numeric value *severity* is removed. It is not possible to overwrite or remove one of the default severity classes. The severity value must be nonnegative.

RETURN VALUE

Upon success, the value **MM_OK** is returned. Upon error, the return value is **MM_NOTOK**. Possible errors include: out of memory, attempt to remove a nonexistent or default severity class.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
addseverity()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.1. System V.

NOTES

New severity classes can also be added by setting the environment variable **SEV_LEVEL**.

fmtmsg(3)

NAME

adjtime − correct the time to synchronize the system clock

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/time.h>

int adjtime(const struct timeval ****delta*, struct timeval ****olddelta***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

adjtime():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The **adjtime**() function gradually adjusts the system clock (as returned by *gettimeofday*(2)). The amount of time by which the clock is to be adjusted is specified in the structure pointed to by *delta*. This structure has the following form:

```
struct timeval {
    time_t      tv_sec;     /* seconds */
    suseconds_t tv_usec;    /* microseconds */
};
```

If the adjustment in *delta* is positive, then the system clock is speeded up by some small percentage (i.e., by adding a small amount of time to the clock value in each second) until the adjustment has been completed. If the adjustment in *delta* is negative, then the clock is slowed down in a similar fashion.

If a clock adjustment from an earlier **adjtime**() call is already in progress at the time of a later **adjtime**() call, and *delta* is not NULL for the later call, then the earlier adjustment is stopped, but any already completed part of that adjustment is not undone.

If *olddelta* is not NULL, then the buffer that it points to is used to return the amount of time remaining from any previous adjustment that has not yet been completed.

RETURN VALUE

On success, **adjtime**() returns 0. On failure, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL
The adjustment in *delta* is outside the permitted range.

EPERM
The caller does not have sufficient privilege to adjust the time. Under Linux, the **CAP_SYS_TIME** capability is required.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
adjtime()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

4.3BSD, System V.

NOTES

The adjustment that **adjtime**() makes to the clock is carried out in such a manner that the clock is always monotonically increasing. Using **adjtime**() to adjust the time prevents the problems that could be caused for certain applications (e.g., *make*(1)) by abrupt positive or negative jumps in the system time.

adjtime() is intended to be used to make small adjustments to the system time. Most systems impose a limit on the adjustment that can be specified in *delta*. In the glibc implementation, *delta* must be less

than or equal to (INT_MAX / 1000000 − 2) and greater than or equal to (INT_MIN / 1000000 + 2) (respectively 2145 and −2145 seconds on i386).

BUGS

A longstanding bug meant that if *delta* was specified as NULL, no valid information about the outstanding clock adjustment was returned in *olddelta*. (In this circumstance, **adjtime**() should return the outstanding clock adjustment, without changing it.) This bug is fixed on systems with glibc 2.8 or later and Linux kernel 2.6.26 or later.

NAME

aio_cancel − cancel an outstanding asynchronous I/O request

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <aio.h>

int aio_cancel(int *fd***, struct aiocb ****aiocbp***);**

DESCRIPTION

The **aio_cancel**() function attempts to cancel outstanding asynchronous I/O requests for the file descriptor *fd*. If *aiocbp* is NULL, all such requests are canceled. Otherwise, only the request described by the control block pointed to by *aiocbp* is canceled. (See *aio*(7) for a description of the *aiocb* structure.)

Normal asynchronous notification occurs for canceled requests (see *aio*(7) and *sigevent*(3type)). The request return status (**aio_return**(3)) is set to −1, and the request error status (**aio_error**(3)) is set to **ECANCELED**. The control block of requests that cannot be canceled is not changed.

If the request could not be canceled, then it will terminate in the usual way after performing the I/O operation. (In this case, *aio_error*(3) will return the status **EINPROGRESSS**.)

If *aiocbp* is not NULL, and *fd* differs from the file descriptor with which the asynchronous operation was initiated, unspecified results occur.

Which operations are cancelable is implementation-defined.

RETURN VALUE

The **aio_cancel**() function returns one of the following values:

AIO_CANCELED
: All requests were successfully canceled.

AIO_NOTCANCELED
: At least one of the requests specified was not canceled because it was in progress. In this case, one may check the status of individual requests using *aio_error*(3).

AIO_ALLDONE
: All requests had already been completed before the call.

−1
: An error occurred. The cause of the error can be found by inspecting *errno*.

ERRORS

EBADF
: *fd* is not a valid file descriptor.

ENOSYS
: **aio_cancel**() is not implemented.

NAME

aio_error − get error status of asynchronous I/O operation

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <aio.h>

int aio_error(const struct aiocb ****aiocbp*);**

DESCRIPTION

The **aio_error**() function returns the error status for the asynchronous I/O request with control block pointed to by *aiocbp*. (See *aio*(7) for a description of the *aiocb* structure.)

RETURN VALUE

This function returns one of the following:

EINPROGRESS
: if the request has not been completed yet.

ECANCELED
: if the request was canceled.

0
: if the request completed successfully.

> **0**
: A positive error number, if the asynchronous I/O operation failed. This is the same value that would have been stored in the *errno* variable in the case of a synchronous *read*(2), *write*(2), *fsync*(2), or *fdatasync*(2) call.

ERRORS

EINVAL
: *aiocbp* does not point at a control block for an asynchronous I/O request of which the return status (see *aio_return*(3)) has not been retrieved yet.

ENOSYS
: **aio_error**() is not implemented.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

aio_fsync − asynchronous file synchronization

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <aio.h>

int aio_fsync(int *op***, struct aiocb ***_aiocbp_**);**

DESCRIPTION

The **aio_fsync**() function does a sync on all outstanding asynchronous I/O operations associated with *aiocbp−>aio_fildes*. (See *aio*(7) for a description of the *aiocb* structure.)

More precisely, if *op* is **O_SYNC**, then all currently queued I/O operations shall be completed as if by a call of *fsync*(2), and if *op* is **O_DSYNC**, this call is the asynchronous analog of *fdatasync*(2).

Note that this is a request only; it does not wait for I/O completion.

Apart from *aio_fildes*, the only field in the structure pointed to by *aiocbp* that is used by this call is the *aio_sigevent* field (a *sigevent* structure, described in *sigevent*(3type)), which indicates the desired type of asynchronous notification at completion. All other fields are ignored.

RETURN VALUE

On success (the sync request was successfully queued) this function returns 0. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EAGAIN
: Out of resources.

EBADF
: *aio_fildes* is not a valid file descriptor open for writing.

EINVAL
: Synchronized I/O is not supported for this file, or *op* is not **O_SYNC** or **O_DSYNC**.

ENOSYS
: **aio_fsync**() is not implemented.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

aio_init − asynchronous I/O initialization

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#define _GNU_SOURCE /* See feature_test_macros(7) */
#include <aio.h>

void aio_init(const struct aioinit **init*);

DESCRIPTION

The GNU-specific **aio_init**() function allows the caller to provide tuning hints to the glibc POSIX AIO implementation. Use of this function is optional, but to be effective, it must be called before employing any other functions in the POSIX AIO API.

The tuning information is provided in the buffer pointed to by the argument *init*. This buffer is a structure of the following form:

```
struct aioinit {
    int aio_threads;    /* Maximum number of threads */
    int aio_num;        /* Number of expected simultaneous
                           requests */
    int aio_locks;      /* Not used */
    int aio_usedba;     /* Not used */
    int aio_debug;      /* Not used */
    int aio_numusers;   /* Not used */
    int aio_idle_time;  /* Number of seconds before idle thread
                           terminates (since glibc 2.2) */
    int aio_reserved;
};
```

The following fields are used in the *aioinit* structure:

aio_threads
: This field specifies the maximum number of worker threads that may be used by the implementation. If the number of outstanding I/O operations exceeds this limit, then excess operations will be queued until a worker thread becomes free. If this field is specified with a value less than 1, the value 1 is used. The default value is 20.

aio_num
: This field should specify the maximum number of simultaneous I/O requests that the caller expects to enqueue. If a value less than 32 is specified for this field, it is rounded up to 32. The default value is 64.

aio_idle_time
: This field specifies the amount of time in seconds that a worker thread should wait for further requests before terminating, after having completed a previous request. The default value is 1.

STANDARDS

NAME

aio_read − asynchronous read

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <aio.h>

int aio_read(struct aiocb **aiocbp*);

DESCRIPTION

The **aio_read**() function queues the I/O request described by the buffer pointed to by *aiocbp*. This function is the asynchronous analog of *read*(2). The arguments of the call

```
read(fd, buf, count)
```

correspond (in order) to the fields *aio_fildes*, *aio_buf*, and *aio_nbytes* of the structure pointed to by *aiocbp*. (See *aio*(7) for a description of the *aiocb* structure.)

The data is read starting at the absolute position *aiocbp−>aio_offset*, regardless of the file offset. After the call, the value of the file offset is unspecified.

The "asynchronous" means that this call returns as soon as the request has been enqueued; the read may or may not have completed when the call returns. One tests for completion using *aio_error*(3). The return status of a completed I/O operation can be obtained by *aio_return*(3). Asynchronous notification of I/O completion can be obtained by setting *aiocbp−>aio_sigevent* appropriately; see *sigevent*(3type) for details.

If **_POSIX_PRIORITIZED_IO** is defined, and this file supports it, then the asynchronous operation is submitted at a priority equal to that of the calling process minus *aiocbp−>aio_reqprio*.

The field *aiocbp−>aio_lio_opcode* is ignored.

No data is read from a regular file beyond its maximum offset.

RETURN VALUE

On success, 0 is returned. On error, the request is not enqueued, −1 is returned, and *errno* is set to indicate the error. If an error is detected only later, it will be reported via *aio_return*(3) (returns status −1) and *aio_error*(3) (error status—whatever one would have gotten in *errno*, such as **EBADF**).

ERRORS

EAGAIN
: Out of resources.

EBADF
: *aio_fildes* is not a valid file descriptor open for reading.

EINVAL
: One or more of *aio_offset*, *aio_reqprio*, or *aio_nbytes* are invalid.

ENOSYS
: **aio_read**() is not implemented.

EOVERFLOW
: The file is a regular file, we start reading before end-of-file and want at least one byte, but the starting position is past the maximum offset for this file.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
aio_read()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

NOTES

It is a good idea to zero out the control block before use. The control block must not be changed while the read operation is in progress. The buffer area being read into must not be accessed during the operation or undefined results may occur. The memory areas involved must remain valid.

Simultaneous I/O operations specifying the same *aiocb* structure produce undefined results.

EXAMPLES

See *aio*(7).

SEE ALSO

NAME

aio_return − get return status of asynchronous I/O operation

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <aio.h>

ssize_t aio_return(struct aiocb *****aiocbp*);**

DESCRIPTION

The **aio_return**() function returns the final return status for the asynchronous I/O request with control block pointed to by *aiocbp*. (See *aio*(7) for a description of the *aiocb* structure.)

This function should be called only once for any given request, after *aio_error*(3) returns something other than **EINPROGRESS**.

RETURN VALUE

If the asynchronous I/O operation has completed, this function returns the value that would have been returned in case of a synchronous *read*(2), *write*(2), *fsync*(2), or *fdatasync*(2), call. On error, −1 is returned, and *errno* is set to indicate the error.

If the asynchronous I/O operation has not yet completed, the return value and effect of **aio_return**() are undefined.

ERRORS

EINVAL

aiocbp does not point at a control block for an asynchronous I/O request of which the return status has not been retrieved yet.

ENOSYS

aio_return() is not implemented.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
aio_return()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

EXAMPLES

See *aio*(7).

SEE ALSO

aio_cancel(3), *aio_error*(3), *aio_fsync*(3), *aio_read*(3), *aio_suspend*(3), *aio_write*(3), *lio_listio*(3), *aio*(7)

NAME

aio_suspend − wait for asynchronous I/O operation or timeout

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <aio.h>

int aio_suspend(const struct aiocb *const aiocb_list[], int nitems,
                const struct timespec *restrict timeout);
```

DESCRIPTION

The **aio_suspend**() function suspends the calling thread until one of the following occurs:

- One or more of the asynchronous I/O requests in the list *aiocb_list* has completed.
- A signal is delivered.
- *timeout* is not NULL and the specified time interval has passed. (For details of the *timespec* structure, see *nanosleep*(2).)

The *nitems* argument specifies the number of items in *aiocb_list*. Each item in the list pointed to by *aiocb_list* must be either NULL (and then is ignored), or a pointer to a control block on which I/O was initiated using *aio_read*(3), *aio_write*(3), or *lio_listio*(3). (See *aio*(7) for a description of the *aiocb* structure.)

If **CLOCK_MONOTONIC** is supported, this clock is used to measure the timeout interval (see *clock_gettime*(2)).

RETURN VALUE

If this function returns after completion of one of the I/O requests specified in *aiocb_list*, 0 is returned. Otherwise, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EAGAIN
: The call timed out before any of the indicated operations had completed.

EINTR
: The call was ended by signal (possibly the completion signal of one of the operations we were waiting for); see *signal*(7).

ENOSYS
: **aio_suspend**() is not implemented.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
aio_suspend()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

POSIX doesn't specify the parameters to be *restrict*; that is specific to glibc.

NOTES

One can achieve polling by using a non-NULL *timeout* that specifies a zero time interval.

If one or more of the asynchronous I/O operations specified in *aiocb_list* has already completed at the time of the call to **aio_suspend**(), then the call returns immediately.

To determine which I/O operations have completed after a successful return from **aio_suspend**(), use *aio_error*(3) to scan the list of *aiocb* structures pointed to by *aiocb_list*.

BUGS

The glibc implementation of **aio_suspend**() is not async-signal-safe, in violation of the requirements of POSIX.1.

SEE ALSO

aio_cancel(3), *aio_error*(3), *aio_fsync*(3), *aio_read*(3), *aio_return*(3), *aio_write*(3), *lio_listio*(3), *aio*(7), *time*(7)

NAME

aio_write − asynchronous write

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <aio.h>

int aio_write(struct aiocb ****aiocbp*);**

DESCRIPTION

The **aio_write**() function queues the I/O request described by the buffer pointed to by *aiocbp*. This function is the asynchronous analog of *write*(2). The arguments of the call

```
write(fd, buf, count)
```

correspond (in order) to the fields *aio_fildes*, *aio_buf*, and *aio_nbytes* of the structure pointed to by *aiocbp*. (See *aio*(7) for a description of the *aiocb* structure.)

If **O_APPEND** is not set, the data is written starting at the absolute position *aiocbp−>aio_offset*, regardless of the file offset. If **O_APPEND** is set, data is written at the end of the file in the same order as **aio_write**() calls are made. After the call, the value of the file offset is unspecified.

The "asynchronous" means that this call returns as soon as the request has been enqueued; the write may or may not have completed when the call returns. One tests for completion using *aio_error*(3). The return status of a completed I/O operation can be obtained *aio_return*(3). Asynchronous notification of I/O completion can be obtained by setting *aiocbp−>aio_sigevent* appropriately; see *sigevent*(3type) for details.

If **_POSIX_PRIORITIZED_IO** is defined, and this file supports it, then the asynchronous operation is submitted at a priority equal to that of the calling process minus *aiocbp−>aio_reqprio*.

The field *aiocbp−>aio_lio_opcode* is ignored.

No data is written to a regular file beyond its maximum offset.

RETURN VALUE

On success, 0 is returned. On error, the request is not enqueued, −1 is returned, and *errno* is set to indicate the error. If an error is detected only later, it will be reported via *aio_return*(3) (returns status −1) and *aio_error*(3) (error status—whatever one would have gotten in *errno*, such as **EBADF**).

ERRORS

EAGAIN
: Out of resources.

EBADF
: *aio_fildes* is not a valid file descriptor open for writing.

EFBIG
: The file is a regular file, we want to write at least one byte, but the starting position is at or beyond the maximum offset for this file.

EINVAL
: One or more of *aio_offset*, *aio_reqprio*, *aio_nbytes* are invalid.

ENOSYS
: **aio_write**() is not implemented.

NAME

alloca − allocate memory that is automatically freed

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <alloca.h>

void *alloca(size_t *size***);**

DESCRIPTION

The **alloca**() function allocates *size* bytes of space in the stack frame of the caller. This temporary space is automatically freed when the function that called **alloca**() returns to its caller.

RETURN VALUE

The **alloca**() function returns a pointer to the beginning of the allocated space. If the allocation causes stack overflow, program behavior is undefined.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
alloca()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

PWB, 32V.

NOTES

The **alloca**() function is machine- and compiler-dependent. Because it allocates from the stack, it's faster than *malloc*(3) and *free*(3). In certain cases, it can also simplify memory deallocation in applications that use *longjmp*(3) or *siglongjmp*(3). Otherwise, its use is discouraged.

Because the space allocated by **alloca**() is allocated within the stack frame, that space is automatically freed if the function return is jumped over by a call to *longjmp*(3) or *siglongjmp*(3).

The space allocated by **alloca**() is *not* automatically deallocated if the pointer that refers to it simply goes out of scope.

Do not attempt to *free*(3) space allocated by **alloca**()!

By necessity, **alloca**() is a compiler built-in, also known as **__builtin_alloca**(). By default, modern compilers automatically translate all uses of **alloca**() into the built-in, but this is forbidden if standards conformance is requested (*−ansi*, *−std=c**), in which case *<alloca.h>* is required, lest a symbol dependency be emitted.

The fact that **alloca**() is a built-in means it is impossible to take its address or to change its behavior by linking with a different library.

Variable length arrays (VLAs) are part of the C99 standard, optional since C11, and can be used for a similar purpose. However, they do not port to standard C++, and, being variables, live in their block scope and don't have an allocator-like interface, making them unfit for implementing functionality like *strdupa*(3).

BUGS

Due to the nature of the stack, it is impossible to check if the allocation would overflow the space available, and, hence, neither is indicating an error. (However, the program is likely to receive a **SIGSEGV** signal if it attempts to access unavailable space.)

On many systems **alloca**() cannot be used inside the list of arguments of a function call, because the stack space reserved by **alloca**() would appear on the stack in the middle of the space for the function arguments.

brk(2), *longjmp*(3), *malloc*(3)

NAME

arc4random, arc4random_uniform, arc4random_buf − cryptographically-secure pseudorandom number generator

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

uint32_t arc4random(void);
uint32_t arc4random_uniform(uint32_t *upper_bound***);**
void arc4random_buf(void *buf* **[.***n***], size_t** *n***);**

DESCRIPTION

These functions give cryptographically-secure pseudorandom numbers.

arc4random() returns a uniformly-distributed value.

arc4random_uniform() returns a uniformly-distributed value less than *upper_bound* (see BUGS).

arc4random_buf() fills the memory pointed to by *buf* , with *n* bytes of pseudorandom data.

The *rand*(3) and *drand48*(3) families of functions should only be used where the quality of the pseudo-random numbers is not a concern *and* there's a need for repeatability of the results. Unless you meet both of those conditions, use the **arc4random**() functions.

RETURN VALUE

arc4random() returns a pseudorandom number.

arc4random_uniform() returns a pseudorandom number less than *upper_bound* for valid input, or **0** when *upper_bound* is invalid.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
arc4random(), **arc4random_uniform**(), **arc4random_buf**()	Thread safety	MT-Safe

STANDARDS

BSD.

HISTORY

OpenBSD 2.1, FreeBSD 3.0, NetBSD 1.6, DragonFly 1.0, libbsd, glibc 2.36.

BUGS

An *upper_bound* of **0** doesn't make sense in a call to **arc4random_uniform**(). Such a call will fail, and return **0**. Be careful, since that value is *not* less than *upper_bound*. In some cases, such as accessing an array, using that value could result in Undefined Behavior.

const char *restrict *entry***);**

error_t argz_replace(char **restrict *argz***, size_t *restrict** *argz_len***,**
const char *restrict *str***, const char *restrict** *with***,**
unsigned int *restrict *replace_count***);**

void argz_stringify(char ***_argz_, size_t** *len***, int** *sep***);**

DESCRIPTION

These functions are glibc-specific.

An argz vector is a pointer to a character buffer together with a length. The intended interpretation of the character buffer is an array of strings, where the strings are separated by null bytes ('\0'). If the length is nonzero, the last byte of the buffer must be a null byte.

These functions are for handling argz vectors. The pair (NULL,0) is an argz vector, and, conversely, argz vectors of length 0 must have null pointer. Allocation of nonempty argz vectors is done using *malloc*(3), so that *free*(3) can be used to dispose of them again.

argz_add() adds the string *str* at the end of the array **argz*, and updates **argz* and **argz_len*.

argz_add_sep() is similar, but splits the string *str* into substrings separated by the delimiter *delim*. For example, one might use this on a UNIX search path with delimiter ':'.

argz_append() appends the argz vector (*buf*, *buf_len*) after (**argz*, **argz_len*) and updates **argz* and **argz_len*. (Thus, **argz_len* will be increased by *buf_len*.)

argz_count() counts the number of strings, that is, the number of null bytes ('\0'), in (*argz*, *argz_len*).

argz_create() converts a UNIX-style argument vector *argv*, terminated by *(char *) 0*, into an argz vector (**argz*, **argz_len*).

argz_create_sep() converts the null-terminated string *str* into an argz vector (**argz*, **argz_len*) by breaking it up at every occurrence of the separator *sep*.

argz_delete() removes the substring pointed to by *entry* from the argz vector (**argz*, **argz_len*) and

updates **argz* and **argz_len*.

argz_extract() is the opposite of **argz_create**(). It takes the argz vector (*argz*, *argz_len*) and fills the array starting at *argv* with pointers to the substrings, and a final NULL, making a UNIX-style argv vector. The array *argv* must have room for *argz_count*(*argz*, *argz_len*) + 1 pointers.

argz_insert() is the opposite of **argz_delete**(). It inserts the argument *entry* at position *before* into the argz vector (**argz*, **argz_len*) and updates **argz* and **argz_len*. If *before* is NULL, then *entry* will inserted at the end.

argz_next() is a function to step through the argz vector. If *entry* is NULL, the first entry is returned. Otherwise, the entry following is returned. It returns NULL if there is no following entry.

argz_replace() replaces each occurrence of *str* with *with*, reallocating argz as necessary. If *replace_count* is non-NULL, **replace_count* will be incremented by the number of replacements.

argz_stringify() is the opposite of **argz_create_sep**(). It transforms the argz vector into a normal string by replacing all null bytes ('\0') except the last by *sep*.

RETURN VALUE

All argz functions that do memory allocation have a return type of *error_t* (an integer type), and return 0 for success, and **ENOMEM** if an allocation error occurs.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
argz_add(), **argz_add_sep**(), **argz_append**(), **argz_count**(), **argz_create**(), **argz_create_sep**(), **argz_delete**(), **argz_extract**(), **argz_insert**(), **argz_next**(), **argz_replace**(), **argz_stringify**()	Thread safety	MT-Safe

STANDARDS

GNU.

BUGS

Argz vectors without a terminating null byte may lead to Segmentation Faults.

NAME

asin, asinf, asinl − arc sine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double asin(double x);
float asinf(float x);
long double asinl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

asinf(), **asinl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions calculate the principal value of the arc sine of *x*; that is the value whose sine is *x*.

RETURN VALUE

On success, these functions return the principal value of the arc sine of *x* in radians; the return value is in the range [−pi/2, pi/2].

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is outside the range [−1, 1], a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is outside the range [−1, 1]
errno is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

asprintf, vasprintf − print to allocated string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <stdio.h>

int asprintf(char **restrict strp, const char *restrict fmt, ...);
int vasprintf(char **restrict strp, const char *restrict fmt,
              va_list ap);
```

DESCRIPTION

The functions **asprintf**() and **vasprintf**() are analogs of *sprintf*(3) and *vsprintf*(3), except that they allocate a string large enough to hold the output including the terminating null byte ('\0'), and return a pointer to it via the first argument. This pointer should be passed to *free*(3) to release the allocated storage when it is no longer needed.

RETURN VALUE

When successful, these functions return the number of bytes printed, just like *sprintf*(3). If memory allocation wasn't possible, or some other error occurs, these functions will return −1, and the contents of *strp* are undefined.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
asprintf(), **vasprintf**()	Thread safety	MT-Safe locale

VERSIONS

The FreeBSD implementation sets *strp* to NULL on error.

STANDARDS

GNU, BSD.

SEE ALSO

free(3), *malloc*(3), *printf*(3)

NAME

assert − abort the program if assertion is false

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <assert.h>

void assert(scalar *expression***);**

DESCRIPTION

This macro can help programmers find bugs in their programs, or handle exceptional cases via a crash that will produce limited debugging output.

If *expression* is false (i.e., compares equal to zero), **assert**() prints an error message to standard error and terminates the program by calling *abort*(3). The error message includes the name of the file and function containing the **assert**() call, the source code line number of the call, and the text of the argument; something like:

```
prog: some_file.c:16: some_func: Assertion `val == 0' failed.
```

If the macro **NDEBUG** is defined at the moment <*assert.h*> was last included, the macro **assert**() generates no code, and hence does nothing at all. It is not recommended to define **NDEBUG** if using **assert**() to detect error conditions since the software may behave non-deterministically.

RETURN VALUE

No value is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
assert()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, C99, POSIX.1-2001.

In C89, *expression* is required to be of type *int* and undefined behavior results if it is not, but in C99 it may have any scalar type.

BUGS

assert() is implemented as a macro; if the expression tested has side-effects, program behavior will be different depending on whether **NDEBUG** is defined. This may create Heisenbugs which go away when debugging is turned on.

SEE ALSO

abort(3), *assert_perror*(3), *exit*(3)

NAME

assert_perror − test errnum and abort

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <assert.h>

void assert_perror(int errnum);
```

DESCRIPTION

If the macro **NDEBUG** was defined at the moment <*assert.h*> was last included, the macro **assert_perror**() generates no code, and hence does nothing at all. Otherwise, the macro **assert_perror**() prints an error message to standard error and terminates the program by calling *abort*(3) if *errnum* is nonzero. The message contains the filename, function name and line number of the macro call, and the output of *strerror(errnum)*.

RETURN VALUE

No value is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
assert_perror()	Thread safety	MT-Safe

STANDARDS

GNU.

BUGS

The purpose of the assert macros is to help programmers find bugs in their programs, things that cannot happen unless there was a coding mistake. However, with system or library calls the situation is rather different, and error returns can happen, and will happen, and should be tested for. Not by an assert, where the test goes away when **NDEBUG** is defined, but by proper error handling code. Never use this macro.

SEE ALSO

abort(3), *assert*(3), *exit*(3), *strerror*(3)

NAME

atan, atanf, atanl − arc tangent function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double atan(double x);
float atanf(float x);
long double atanl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

atanf(), **atanl**():

```
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
    || /* Since glibc 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

DESCRIPTION

These functions calculate the principal value of the arc tangent of *x*; that is the value whose tangent is *x*.

RETURN VALUE

On success, these functions return the principal value of the arc tangent of *x* in radians; the return value is in the range [−pi/2, pi/2].

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is positive infinity (negative infinity), +pi/2 (−pi/2) is returned.

ERRORS

No errors occur.

NAME

atan2, atan2f, atan2l − arc tangent function of two variables

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double atan2(double y, double x);
float atan2f(float y, float x);
long double atan2l(long double y, long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

atan2f(), **atan2l**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions calculate the principal value of the arc tangent of *y/x*, using the signs of the two arguments to determine the quadrant of the result.

RETURN VALUE

On success, these functions return the principal value of the arc tangent of *y/x* in radians; the return value is in the range [−pi, pi].

If *y* is +0 (−0) and *x* is less than 0, +pi (−pi) is returned.

If *y* is +0 (−0) and *x* is greater than 0, +0 (−0) is returned.

If *y* is less than 0 and *x* is +0 or −0, −pi/2 is returned.

If *y* is greater than 0 and *x* is +0 or −0, pi/2 is returned.

If either *x* or *y* is NaN, a NaN is returned.

If *y* is +0 (−0) and *x* is −0, +pi (−pi) is returned.

If *y* is +0 (−0) and *x* is +0, +0 (−0) is returned.

If *y* is a finite value greater (less) than 0, and *x* is negative infinity, +pi (−pi) is returned.

If *y* is a finite value greater (less) than 0, and *x* is positive infinity, +0 (−0) is returned.

If *y* is positive infinity (negative infinity), and *x* is finite, pi/2 (−pi/2) is returned.

If *y* is positive infinity (negative infinity) and *x* is negative infinity, +3*pi/4 (−3*pi/4) is returned.

If *y* is positive infinity (negative infinity) and *x* is positive infinity, +pi/4 (−pi/4) is returned.

ERRORS

No errors occur.

ATTRIBUTES

NAME

atanh, atanhf, atanhl − inverse hyperbolic tangent function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double atanh(double x);
float atanhf(float x);
long double atanhl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

atanh():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

atanhf(), **atanhl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions calculate the inverse hyperbolic tangent of *x*; that is the value whose hyperbolic tangent is *x*.

RETURN VALUE

On success, these functions return the inverse hyperbolic tangent of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is +1 or −1, a pole error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the mathematically correct sign.

If the absolute value of *x* is greater than 1, a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* less than −1 or greater than +1
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

Pole error: *x* is +1 or −1
: *errno* is set to **ERANGE** (but see BUGS). A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
atanh(), **atanhf**(), **atanhl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD.

BUGS

In glibc 2.9 and earlier, when a pole error occurs, *errno* is set to **EDOM** instead of the POSIX-mandated **ERANGE**. Since glibc 2.10, glibc does the right thing.

NAME

atexit − register a function to be called at normal process termination

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int atexit(void (* *function***)(void));**

DESCRIPTION

The **atexit**() function registers the given *function* to be called at normal process termination, either via *exit*(3) or via return from the program's *main*(). Functions so registered are called in the reverse order of their registration; no arguments are passed.

The same function may be registered multiple times: it is called once for each registration.

POSIX.1 requires that an implementation allow at least **ATEXIT_MAX** (32) such functions to be registered. The actual limit supported by an implementation can be obtained using *sysconf*(3).

When a child process is created via *fork*(2), it inherits copies of its parent's registrations. Upon a successful call to one of the *exec*(3) functions, all registrations are removed.

RETURN VALUE

The **atexit**() function returns the value 0 if successful; otherwise it returns a nonzero value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
atexit()	Thread safety	MT-Safe

VERSIONS

POSIX.1 says that the result of calling *exit*(3) more than once (i.e., calling *exit*(3) within a function registered using *atexit*()) is undefined. On some systems (but not Linux), this can result in an infinite recursion; portable programs should not invoke *exit*(3) inside a function registered using **atexit**().

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, C99, SVr4, 4.3BSD.

NOTES

Functions registered using **atexit**() (and *on_exit*(3)) are not called if a process terminates abnormally because of the delivery of a signal.

If one of the registered functions calls *_exit*(2), then any remaining functions are not invoked, and the other process termination steps performed by *exit*(3) are not performed.

The **atexit**() and *on_exit*(3) functions register functions on the same list: at normal process termination, the registered functions are invoked in reverse order of their registration by these two functions.

According to POSIX.1, the result is undefined if *longjmp*(3) is used to terminate execution of one of the functions registered using **atexit**().

Linux notes

Since glibc 2.2.3, **atexit**() (and *on_exit*(3)) can be used within a shared library to establish functions that are called when the shared library is unloaded.

EXAMPLES

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

void
bye(void)
{
    printf("That was all, folks\n");
```

```
}

int
main(void)
{
    long a;
    int i;

    a = sysconf(_SC_ATEXIT_MAX);
    printf("ATEXIT_MAX = %ld\n", a);

    i = atexit(bye);
    if (i != 0) {
        fprintf(stderr, "cannot set exit function\n");
        exit(EXIT_FAILURE);
    }

    exit(EXIT_SUCCESS);
}
```

SEE ALSO

_exit(2), *dlopen*(3), *exit*(3), *on_exit*(3)

NAME

atof − convert a string to a double

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

double atof(const char ****nptr*);**

DESCRIPTION

The **atof**() function converts the initial portion of the string pointed to by *nptr* to *double*. The behavior is the same as

```
strtod(nptr, NULL);
```

except that **atof**() does not detect errors.

RETURN VALUE

The converted value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
atof()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, C99, SVr4, 4.3BSD.

SEE ALSO

atoi(3), *atol*(3), *strfromd*(3), *strtod*(3), *strtol*(3), *strtoul*(3)

NAME

atoi, atol, atoll − convert a string to an integer

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int atoi(const char *nptr);
long atol(const char *nptr);
long long atoll(const char *nptr);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

atoll():
_ISOC99_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **atoi**() function converts the initial portion of the string pointed to by *nptr* to *int*. The behavior is the same as

```
strtol(nptr, NULL, 10);
```

except that **atoi**() does not detect errors.

The **atol**() and **atoll**() functions behave the same as **atoi**(), except that they convert the initial portion of the string to their return type of *long* or *long long*.

RETURN VALUE

The converted value or 0 on error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
atoi(), **atol**(), **atoll**()	Thread safety	MT-Safe locale

VERSIONS

POSIX.1 leaves the return value of **atoi**() on error unspecified. On glibc, musl libc, and uClibc, 0 is returned on error.

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001, SVr4, 4.3BSD.

C89 and POSIX.1-1996 include the functions **atoi**() and **atol**() only.

BUGS

errno is not set on error so there is no way to distinguish between 0 as an error and as the converted value. No checks for overflow or underflow are done. Only base-10 input can be converted. It is recommended to instead use the **strtol**() and **strtoul**() family of functions in new programs.

SEE ALSO

atof(3), *strtod*(3), *strtol*(3), *strtoul*(3)

NAME

backtrace, backtrace_symbols, backtrace_symbols_fd − support for application self-debugging

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <execinfo.h>

int backtrace(void *buffer[.size], int size);

char **backtrace_symbols(void *const buffer[.size], int size);
void backtrace_symbols_fd(void *const buffer[.size], int size, int  fd);
```

DESCRIPTION

backtrace() returns a backtrace for the calling program, in the array pointed to by *buffer*. A backtrace is the series of currently active function calls for the program. Each item in the array pointed to by *buffer* is of type *void **, and is the return address from the corresponding stack frame. The *size* argument specifies the maximum number of addresses that can be stored in *buffer*. If the backtrace is larger than *size*, then the addresses corresponding to the *size* most recent function calls are returned; to obtain the complete backtrace, make sure that *buffer* and *size* are large enough.

Given the set of addresses returned by **backtrace**() in *buffer*, **backtrace_symbols**() translates the addresses into an array of strings that describe the addresses symbolically. The *size* argument specifies the number of addresses in *buffer*. The symbolic representation of each address consists of the function name (if this can be determined), a hexadecimal offset into the function, and the actual return address (in hexadecimal). The address of the array of string pointers is returned as the function result of **backtrace_symbols**(). This array is *malloc*(3)ed by **backtrace_symbols**(), and must be freed by the caller. (The strings pointed to by the array of pointers need not and should not be freed.)

backtrace_symbols_fd() takes the same *buffer* and *size* arguments as **backtrace_symbols**(), but instead of returning an array of strings to the caller, it writes the strings, one per line, to the file descriptor *fd*. **backtrace_symbols_fd**() does not call *malloc*(3), and so can be employed in situations where the latter function might fail, but see NOTES.

RETURN VALUE

backtrace() returns the number of addresses returned in *buffer*, which is not greater than *size*. If the return value is less than *size*, then the full backtrace was stored; if it is equal to *size*, then it may have been truncated, in which case the addresses of the oldest stack frames are not returned.

On success, **backtrace_symbols**() returns a pointer to the array *malloc*(3)ed by the call; on error, NULL is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
backtrace(), **backtrace_symbols**(), **backtrace_symbols_fd**()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.1.

NOTES

These functions make some assumptions about how a function's return address is stored on the stack. Note the following:

- Omission of the frame pointers (as implied by any of *gcc*(1)nonzero optimization levels) may cause these assumptions to be violated.
- Inlined functions do not have stack frames.
- Tail-call optimization causes one stack frame to replace another.
- **backtrace**() and **backtrace_symbols_fd**() don't call **malloc**() explicitly, but they are part of *libgcc*, which gets loaded dynamically when first used. Dynamic loading usually triggers a call to *malloc*(3). If you need certain calls to these two functions to not allocate memory (in signal handlers, for example), you need to make sure *libgcc* is loaded beforehand.

The symbol names may be unavailable without the use of special linker options. For systems using the GNU linker, it is necessary to use the −*rdynamic* linker option. Note that names of "static" functions are not exposed, and won't be available in the backtrace.

EXAMPLES

The program below demonstrates the use of **backtrace**() and **backtrace_symbols**(). The following shell session shows what we might see when running the program:

```
$ cc -rdynamic prog.c -o prog
$ ./prog 3
backtrace() returned 8 addresses
./prog(myfunc3+0x5c) [0x80487f0]
./prog [0x8048871]
./prog(myfunc+0x21) [0x8048894]
./prog(myfunc+0x1a) [0x804888d]
./prog(myfunc+0x1a) [0x804888d]
./prog(main+0x65) [0x80488fb]
/lib/libc.so.6(__libc_start_main+0xdc) [0xb7e38f9c]
./prog [0x8048711]
```

Program source

NAME

basename, dirname − parse pathname components

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <libgen.h>

char *dirname(char *path);
char *basename(char *path);
```

DESCRIPTION

Warning: there are two different functions **basename**(); see below.

The functions **dirname**() and **basename**() break a null-terminated pathname string into directory and filename components. In the usual case, **dirname**() returns the string up to, but not including, the final '/', and **basename**() returns the component following the final '/'. Trailing '/' characters are not counted as part of the pathname.

If *path* does not contain a slash, **dirname**() returns the string "." while **basename**() returns a copy of *path*. If *path* is the string "/", then both **dirname**() and **basename**() return the string "/". If *path* is a null pointer or points to an empty string, then both **dirname**() and **basename**() return the string ".".

Concatenating the string returned by **dirname**(), a "/", and the string returned by **basename**() yields a complete pathname.

Both **dirname**() and **basename**() may modify the contents of *path*, so it may be desirable to pass a copy when calling one of these functions.

These functions may return pointers to statically allocated memory which may be overwritten by subsequent calls. Alternatively, they may return a pointer to some part of *path*, so that the string referred to by *path* should not be modified or freed until the pointer returned by the function is no longer required.

The following list of examples (taken from SUSv2) shows the strings returned by **dirname**() and **basename**() for different paths:

path	**dirname**	**basename**
/usr/lib	/usr	lib
/usr/	/	usr
usr	.	usr
/	/	/
.	.	.
..	.	..

RETURN VALUE

Both **dirname**() and **basename**() return pointers to null-terminated strings. (Do not pass these pointers to *free*(3).)

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	**Attribute**	**Value**
basename(), **dirname**()	Thread safety	MT-Safe

VERSIONS

There are two different versions of **basename**() - the POSIX version described above, and the GNU version, which one gets after

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>
```

The GNU version never modifies its argument, and returns the empty string when *path* has a trailing slash, and in particular also when it is "/". There is no GNU version of **dirname**().

With glibc, one gets the POSIX version of **basename**() when <*libgen.h*> is included, and the GNU version otherwise.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

BUGS

In the glibc implementation, the POSIX versions of these functions modify the *path* argument, and segfault when called with a static string such as "/usr/".

Before glibc 2.2.1, the glibc version of **dirname**() did not correctly handle pathnames with trailing '/' characters, and generated a segfault if given a NULL argument.

EXAMPLES

The following code snippet demonstrates the use of **basename**() and **dirname**():

```
char *dirc, *basec, *bname, *dname;
char *path = "/etc/passwd";

dirc = strdup(path);
basec = strdup(path);
dname = dirname(dirc);
bname = basename(basec);
printf("dirname=%s, basename=%s\n", dname, bname);
```

NAME

bcmp − compare byte sequences

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <strings.h>

[[deprecated]] int bcmp(const void *s1***[.**n**], const void** *s2***[.**n**], size_t** *n***);**

DESCRIPTION

bcmp() is identical to *memcmp*(3); use the latter instead.

STANDARDS

None.

HISTORY

4.3BSD. Marked as LEGACY in POSIX.1-2001; removed in POSIX.1-2008.

SEE ALSO

memcmp(3)

NAME

bcopy − copy byte sequence

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <strings.h>

[[deprecated]] void bcopy(const void *src***[.***n***], void** *dest***[.***n***], size_t** *n***);**

DESCRIPTION

The **bcopy**() function copies *n* bytes from *src* to *dest*. The result is correct, even when both areas overlap.

RETURN VALUE

None.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
bcopy()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

4.3BSD.

Marked as LEGACY in POSIX.1-2001: use *memcpy*(3) or *memmove*(3) in new programs. Note that the first two arguments are interchanged for *memcpy*(3) and *memmove*(3). POSIX.1-2008 removes the specification of **bcopy**().

SEE ALSO

bstring(3), *memccpy*(3), *memcpy*(3), *memmove*(3), *strcpy*(3), *strncpy*(3)

NAME

bindresvport − bind a socket to a privileged IP port

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <netinet/in.h>

int bindresvport(int sockfd, struct sockaddr_in *sin);
```

DESCRIPTION

bindresvport() is used to bind the socket referred to by the file descriptor *sockfd* to a privileged anonymous IP port, that is, a port number arbitrarily selected from the range 512 to 1023.

If the *bind*(2) performed by **bindresvport**() is successful, and *sin* is not NULL, then *sin−>sin_port* returns the port number actually allocated.

sin can be NULL, in which case *sin−>sin_family* is implicitly taken to be **AF_INET**. However, in this case, **bindresvport**() has no way to return the port number actually allocated. (This information can later be obtained using *getsockname*(2).)

RETURN VALUE

bindresvport() returns 0 on success; otherwise −1 is returned and *errno* is set to indicate the error.

ERRORS

bindresvport() can fail for any of the same reasons as *bind*(2). In addition, the following errors may occur:

EACCES
: The calling process was not privileged (on Linux: the calling process did not have the **CAP_NET_BIND_SERVICE** capability in the user namespace governing its network namespace).

EADDRINUSE
: All privileged ports are in use.

EAFNOSUPPORT (**EPFNOSUPPORT** in glibc 2.7 and earlier)
: *sin* is not NULL and *sin−>sin_family* is not **AF_INET**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
bindresvport()	Thread safety	glibc >= 2.17: MT-Safe; glibc < 2.17: MT-Unsafe

The **bindresvport**() function uses a static variable that was not protected by a lock before glibc 2.17, rendering the function MT-Unsafe.

VERSIONS

Present on the BSDs, Solaris, and many other systems.

NOTES

Unlike some **bindresvport**() implementations, the glibc implementation ignores any value that the caller supplies in *sin−>sin_port*.

STANDARDS

BSD.

SEE ALSO

bind(2), *getsockname*(2)

NAME

bsd_signal − signal handling with BSD semantics

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <signal.h>

typedef void (*sighandler_t)(int);

sighandler_t bsd_signal(int *signum***, sighandler_t** *handler***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

bsd_signal():
Since glibc 2.26:
_XOPEN_SOURCE >= 500
&& ! (_POSIX_C_SOURCE >= 200809L)
glibc 2.25 and earlier:
_XOPEN_SOURCE

DESCRIPTION

The **bsd_signal**() function takes the same arguments, and performs the same task, as *signal*(2).

The difference between the two is that **bsd_signal**() is guaranteed to provide reliable signal semantics, that is: a) the disposition of the signal is not reset to the default when the handler is invoked; b) delivery of further instances of the signal is blocked while the signal handler is executing; and c) if the handler interrupts a blocking system call, then the system call is automatically restarted. A portable application cannot rely on *signal*(2) to provide these guarantees.

RETURN VALUE

The **bsd_signal**() function returns the previous value of the signal handler, or **SIG_ERR** on error.

ERRORS

As for *signal*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
bsd_signal()	Thread safety	MT-Safe

VERSIONS

Use of **bsd_signal**() should be avoided; use *sigaction*(2) instead.

On modern Linux systems, **bsd_signal**() and *signal*(2) are equivalent. But on older systems, *signal*(2) provided unreliable signal semantics; see *signal*(2) for details.

The use of *sighandler_t* is a GNU extension; this type is defined only if the **_GNU_SOURCE** feature test macro is defined.

STANDARDS

None.

HISTORY

4.2BSD, POSIX.1-2001. Removed in POSIX.1-2008, recommending the use of *sigaction*(2) instead.

SEE ALSO

sigaction(2), *signal*(2), *sysv_signal*(3), *signal*(7)

NAME

bsearch − binary search of a sorted array

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

void *bsearch(const void key[.size], const void base[.size * .nmemb],
              size_t nmemb, size_t size,
              int (*compar)(const void [.size], const void [.size]));
```

DESCRIPTION

The **bsearch**() function searches an array of *nmemb* objects, the initial member of which is pointed to by *base*, for a member that matches the object pointed to by *key*. The size of each member of the array is specified by *size*.

The contents of the array should be in ascending sorted order according to the comparison function referenced by *compar*. The *compar* routine is expected to have two arguments which point to the *key* object and to an array member, in that order, and should return an integer less than, equal to, or greater than zero if the *key* object is found, respectively, to be less than, to match, or be greater than the array member.

RETURN VALUE

The **bsearch**() function returns a pointer to a matching member of the array, or NULL if no match is found. If there are multiple elements that match the key, the element returned is unspecified.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
bsearch()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, C99, SVr4, 4.3BSD.

EXAMPLES

The example below first sorts an array of structures using *qsort*(3), then retrieves desired elements using **bsearch**().

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define ARRAY_SIZE(arr)  (sizeof((arr)) / sizeof((arr)[0]))

struct mi {
    int         nr;
    const char  *name;
};

static struct mi  months[] = {
    { 1, "jan" }, { 2, "feb" }, { 3, "mar" }, { 4, "apr" },
    { 5, "may" }, { 6, "jun" }, { 7, "jul" }, { 8, "aug" },
    { 9, "sep" }, {10, "oct" }, {11, "nov" }, {12, "dec" }
};

static int
compmi(const void *m1, const void *m2)
{
    const struct mi *mi1 = m1;
    const struct mi *mi2 = m2;
```

```
    return strcmp(mi1->name, mi2->name);
}

int
main(int argc, char *argv[])
{
    qsort(months, ARRAY_SIZE(months), sizeof(months[0]), compmi);
    for (size_t i = 1; i < argc; i++) {
        struct mi key;
        struct mi *res;

        key.name = argv[i];
        res = bsearch(&key, months, ARRAY_SIZE(months),
                      sizeof(months[0]), compmi);
        if (res == NULL)
            printf("'%s': unknown month\n", argv[i]);
        else
            printf("%s: month #%d\n", res->name, res->nr);
    }
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

hsearch(3), *lsearch*(3), *qsort*(3), *tsearch*(3)

NAME

bcmp, bcopy, bzero, memccpy, memchr, memcmp, memcpy, memfrob, memmem, memmove, memset − byte string operations

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

int bcmp(const void s1[.n], const void s2[.n], size_t n);

void bcopy(const void src[.n], void dest[.n], size_t n);

void bzero(void s[.n], size_t n);

void *memccpy(void dest[.n], const void src[.n], int c, size_t n);

void *memchr(const void s[.n], int c, size_t n);

int memcmp(const void s1[.n], const void s2[.n], size_t n);

void *memcpy(void dest[.n], const void src[.n], size_t n);

void *memfrob(void s[.n], size_t n);

void *memmem(const void haystack[.haystacklen], size_t haystacklen,
       const void needle[.needlelen], size_t needlelen);

void *memmove(void dest[.n], const void src[.n], size_t n);

void *memset(void s[.n], int c, size_t n);
```

DESCRIPTION

The byte string functions perform operations on strings (byte arrays) that are not necessarily null-terminated. See the individual man pages for descriptions of each function.

NOTES

The functions **bcmp**() and **bcopy**() are obsolete. Use **memcmp**() and **memmove**() instead.

SEE ALSO

bcmp(3), *bcopy*(3), *bzero*(3), *memccpy*(3), *memchr*(3), *memcmp*(3), *memcpy*(3), *memfrob*(3), *memmem*(3), *memmove*(3), *memset*(3), *string*(3)

NAME

bswap_16, bswap_32, bswap_64 − reverse order of bytes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <byteswap.h>

uint16_t bswap_16(uint16_t x);
uint32_t bswap_32(uint32_t x);
uint64_t bswap_64(uint64_t x);
```

DESCRIPTION

These functions return a value in which the order of the bytes in their 2-, 4-, or 8-byte arguments is reversed.

RETURN VALUE

These functions return the value of their argument with the bytes reversed.

ERRORS

These functions always succeed.

STANDARDS

GNU.

EXAMPLES

The program below swaps the bytes of the 8-byte integer supplied as its command-line argument. The following shell session demonstrates the use of the program:

```
$ ./a.out 0x0123456789abcdef
0x123456789abcdef ==> 0xefcdab8967452301
```

Program source

```
#include <byteswap.h>
#include <inttypes.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
{
    uint64_t x;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s <num>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    x = strtoull(argv[1], NULL, 0);
    printf("%#" PRIx64 " ==> %#" PRIx64 "\n", x, bswap_64(x));

    exit(EXIT_SUCCESS);
}
```

SEE ALSO

byteorder(3), *endian*(3)

NAME

btowc − convert single byte to wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

wint_t btowc(int *c***);**

DESCRIPTION

The **btowc**() function converts *c*, interpreted as a multibyte sequence of length 1, starting in the initial shift state, to a wide character and returns it. If *c* is **EOF** or not a valid multibyte sequence of length 1, the **btowc**() function returns **WEOF**.

RETURN VALUE

The **btowc**() function returns the wide character converted from the single byte *c*. If *c* is **EOF** or not a valid multibyte sequence of length 1, it returns **WEOF**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
btowc()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

NOTES

The behavior of **btowc**() depends on the **LC_CTYPE** category of the current locale.

This function should never be used. It does not work for encodings which have state, and unnecessarily treats single bytes differently from multibyte sequences. Use either *mbtowc*(3) or the thread-safe *mbrtowc*(3) instead.

SEE ALSO

mbrtowc(3), *mbtowc*(3), *wctob*(3)

NAME

btree − btree database access method

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/types.h>
#include <db.h>

DESCRIPTION

Note well: This page documents interfaces provided up until glibc 2.1. Since glibc 2.2, glibc no longer provides these interfaces. Probably, you are looking for the APIs provided by the *libdb* library instead.

The routine *dbopen*(3) is the library interface to database files. One of the supported file formats is btree files. The general description of the database access methods is in *dbopen*(3), this manual page describes only the btree-specific information.

The btree data structure is a sorted, balanced tree structure storing associated key/data pairs.

The btree access-method-specific data structure provided to *dbopen*(3) is defined in the <*db.h*> include file as follows:

```
typedef struct {
    unsigned long flags;
    unsigned int  cachesize;
    int           maxkeypage;
    int           minkeypage;
    unsigned int  psize;
    int         (*compare)(const DBT *key1, const DBT *key2);
    size_t      (*prefix)(const DBT *key1, const DBT *key2);
    int           lorder;
} BTREEINFO;
```

The elements of this structure are as follows:

flags The flag value is specified by ORing any of the following values:

R_DUP

Permit duplicate keys in the tree, that is, permit insertion if the key to be inserted already exists in the tree. The default behavior, as described in *dbopen*(3), is to overwrite a matching key when inserting a new key or to fail if the **R_NOOVERWRITE** flag is specified. The **R_DUP** flag is overridden by the **R_NOOVERWRITE** flag, and if the **R_NOOVERWRITE** flag is specified, attempts to insert duplicate keys into the tree will fail.

If the database contains duplicate keys, the order of retrieval of key/data pairs is undefined if the *get* routine is used, however, *seq* routine calls with the **R_CURSOR** flag set will always return the logical "first" of any group of duplicate keys.

cachesize

A suggested maximum size (in bytes) of the memory cache. This value is *only* advisory, and the access method will allocate more memory rather than fail. Since every search examines the root page of the tree, caching the most recently used pages substantially improves access time. In addition, physical writes are delayed as long as possible, so a moderate cache can reduce the number of I/O operations significantly. Obviously, using a cache increases (but only increases) the likelihood of corruption or lost data if the system crashes while a tree is being modified. If *cachesize* is 0 (no size is specified), a default cache is used.

maxkeypage

The maximum number of keys which will be stored on any single page. Not currently implemented.

minkeypage

The minimum number of keys which will be stored on any single page. This value is used to determine which keys will be stored on overflow pages, that is, if a key or data item is longer than the pagesize divided by the minkeypage value, it will be stored on overflow pages instead

of in the page itself. If *minkeypage* is 0 (no minimum number of keys is specified), a value of 2 is used.

psize Page size is the size (in bytes) of the pages used for nodes in the tree. The minimum page size is 512 bytes and the maximum page size is 64 KiB. If *psize* is 0 (no page size is specified), a page size is chosen based on the underlying filesystem I/O block size.

compare
Compare is the key comparison function. It must return an integer less than, equal to, or greater than zero if the first key argument is considered to be respectively less than, equal to, or greater than the second key argument. The same comparison function must be used on a given tree every time it is opened. If *compare* is NULL (no comparison function is specified), the keys are compared lexically, with shorter keys considered less than longer keys.

prefix Prefix is the prefix comparison function. If specified, this routine must return the number of bytes of the second key argument which are necessary to determine that it is greater than the first key argument. If the keys are equal, the key length should be returned. Note, the usefulness of this routine is very data-dependent, but, in some data sets can produce significantly reduced tree sizes and search times. If *prefix* is NULL (no prefix function is specified), *and* no comparison function is specified, a default lexical comparison routine is used. If *prefix* is NULL and a comparison routine is specified, no prefix comparison is done.

lorder The byte order for integers in the stored database metadata. The number should represent the order as an integer; for example, big endian order would be the number 4,321. If *lorder* is 0 (no order is specified), the current host order is used.

If the file already exists (and the **O_TRUNC** flag is not specified), the values specified for the arguments *flags*, *lorder*, and *psize* are ignored in favor of the values used when the tree was created.

Forward sequential scans of a tree are from the least key to the greatest.

Space freed up by deleting key/data pairs from the tree is never reclaimed, although it is normally made available for reuse. This means that the btree storage structure is grow-only. The only solutions are to avoid excessive deletions, or to create a fresh tree periodically from a scan of an existing one.

Searches, insertions, and deletions in a btree will all complete in O lg base N where base is the average fill factor. Often, inserting ordered data into btrees results in a low fill factor. This implementation has been modified to make ordered insertion the best case, resulting in a much better than normal page fill factor.

ERRORS

The *btree* access method routines may fail and set *errno* for any of the errors specified for the library routine *dbopen*(3).

BUGS

Only big and little endian byte order is supported.

NAME

htonl, htons, ntohl, ntohs − convert values between host and network byte order

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <arpa/inet.h>

uint32_t htonl(uint32_t hostlong);
uint16_t htons(uint16_t hostshort);

uint32_t ntohl(uint32_t netlong);
uint16_t ntohs(uint16_t netshort);
```

DESCRIPTION

The **htonl**() function converts the unsigned integer *hostlong* from host byte order to network byte order.

The **htons**() function converts the unsigned short integer *hostshort* from host byte order to network byte order.

The **ntohl**() function converts the unsigned integer *netlong* from network byte order to host byte order.

The **ntohs**() function converts the unsigned short integer *netshort* from network byte order to host byte order.

On the i386 the host byte order is Least Significant Byte first, whereas the network byte order, as used on the Internet, is Most Significant Byte first.

NAME

bzero, explicit_bzero − zero a byte string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <strings.h>

void bzero(void *s***[.***n***], size_t** *n***);**

#include <string.h>

void explicit_bzero(void *s***[.***n***], size_t** *n***);**

DESCRIPTION

The **bzero**() function erases the data in the *n* bytes of the memory starting at the location pointed to by *s*, by writing zeros (bytes containing '\0') to that area.

The **explicit_bzero**() function performs the same task as **bzero**(). It differs from **bzero**() in that it guarantees that compiler optimizations will not remove the erase operation if the compiler deduces that the operation is "unnecessary".

RETURN VALUE

None.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
bzero(), **explicit_bzero**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

explicit_bzero()

glibc 2.25.

The **explicit_bzero**() function is a nonstandard extension that is also present on some of the BSDs. Some other implementations have a similar function, such as **memset_explicit**() or **memset_s**().

bzero() 4.3BSD.

Marked as LEGACY in POSIX.1-2001. Removed in POSIX.1-2008.

NOTES

The **explicit_bzero**() function addresses a problem that security-conscious applications may run into when using **bzero**(): if the compiler can deduce that the location to be zeroed will never again be touched by a *correct* program, then it may remove the **bzero**() call altogether. This is a problem if the intent of the **bzero**() call was to erase sensitive data (e.g., passwords) to prevent the possibility that the data was leaked by an incorrect or compromised program. Calls to **explicit_bzero**() are never optimized away by the compiler.

The **explicit_bzero**() function does not solve all problems associated with erasing sensitive data:

- The **explicit_bzero**() function does *not* guarantee that sensitive data is completely erased from memory. (The same is true of *bzero*().) For example, there may be copies of the sensitive data in a register and in "scratch" stack areas. The **explicit_bzero**() function is not aware of these copies, and can't erase them.
- In some circumstances, **explicit_bzero**() can *decrease* security. If the compiler determined that the variable containing the sensitive data could be optimized to be stored in a register (because it is small enough to fit in a register, and no operation other than the **explicit_bzero**() call would need to take the address of the variable), then the **explicit_bzero**() call will force the data to be copied from the register to a location in RAM that is then immediately erased (while the copy in the register remains unaffected). The problem here is that data in RAM is more likely to be exposed by a bug than data in a register, and thus the **explicit_bzero**() call creates a brief time window where the sensitive data is more vulnerable than it would otherwise have been if no attempt had been made to

erase the data.

Note that declaring the sensitive variable with the **volatile** qualifier does *not* eliminate the above problems. Indeed, it will make them worse, since, for example, it may force a variable that would otherwise have been optimized into a register to instead be maintained in (more vulnerable) RAM for its entire lifetime.

Notwithstanding the above details, for security-conscious applications, using **explicit_bzero**() is generally preferable to not using it. The developers of **explicit_bzero**() anticipate that future compilers will recognize calls to **explicit_bzero**() and take steps to ensure that all copies of the sensitive data are erased, including copies in registers or in "scratch" stack areas.

NAME

cabs, cabsf, cabsl − absolute value of a complex number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double cabs(double complex *z***);**
float cabsf(float complex *z***);**
long double cabsl(long double complex *z***);**

DESCRIPTION

These functions return the absolute value of the complex number *z*. The result is a real number.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cabs(), **cabsf**(), **cabsl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

NOTES

The function is actually an alias for *hypot(a, b)* (or, equivalently, *sqrt(a*a + b*b)*).

SEE ALSO

abs(3), *cimag*(3), *hypot*(3), *complex*(7)

NAME

cacos, cacosf, cacosl − complex arc cosine

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex cacos(double complex *z***);**
float complex cacosf(float complex *z***);**
long double complex cacosl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex arc cosine of *z*. If *y* = *cacos(z)*, then *z* = *ccos(y)*. The real part of *y* is chosen in the interval [0,pi].

One has:

cacos(z) = −i * clog(z + i * csqrt(1 − z * z))

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cacos(), **cacosf**(), **cacosl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

EXAMPLES

```
/* Link with "-lm" */

#include <complex.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    double complex z, c, f;
    double complex i = I;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <real> <imag>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    z = atof(argv[1]) + atof(argv[2]) * I;

    c = cacos(z);

    printf("cacos() = %6.3f %6.3f*i\n", creal(c), cimag(c));

    f = -i * clog(z + i * csqrt(1 - z * z));

    printf("formula = %6.3f %6.3f*i\n", creal(f), cimag(f));

    exit(EXIT_SUCCESS);
}
```

SEE ALSO

ccos(3), *clog*(3), *complex*(7)

NAME

cacosh, cacoshf, cacoshl − complex arc hyperbolic cosine

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex cacosh(double complex *z***);**
float complex cacoshf(float complex *z***);**
long double complex cacoshl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex arc hyperbolic cosine of *z*. If *y* = *cacosh(z)*, then *z* = *ccosh(y)*. The imaginary part of *y* is chosen in the interval [−pi,pi]. The real part of *y* is chosen nonnegative.

One has:

cacosh(z) = 2 * clog(csqrt((z + 1) / 2) + csqrt((z − 1) / 2))

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cacosh(), **cacoshf**(), **cacoshl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001. glibc 2.1.

EXAMPLES

```
/* Link with "-lm" */

#include <complex.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    double complex z, c, f;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <real> <imag>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    z = atof(argv[1]) + atof(argv[2]) * I;

    c = cacosh(z);
    printf("cacosh() = %6.3f %6.3f*i\n", creal(c), cimag(c));

    f = 2 * clog(csqrt((z + 1)/2) + csqrt((z - 1)/2));
    printf("formula  = %6.3f %6.3f*i\n", creal(f), cimag(f));

    exit(EXIT_SUCCESS);
}
```

NAME

canonicalize_file_name − return the canonicalized absolute pathname

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <stdlib.h>

char *canonicalize_file_name(const char *path);
```

DESCRIPTION

The **canonicalize_file_name**() function returns a null-terminated string containing the canonicalized absolute pathname corresponding to *path*. In the returned string, symbolic links are resolved, as are . and .. pathname components. Consecutive slash (/) characters are replaced by a single slash.

The returned string is dynamically allocated by **canonicalize_file_name**() and the caller should deallocate it with *free*(3) when it is no longer required.

The call *canonicalize_file_name(path)* is equivalent to the call:

```
realpath(path, NULL);
```

RETURN VALUE

On success, **canonicalize_file_name**() returns a null-terminated string. On error (e.g., a pathname component is unreadable or does not exist), **canonicalize_file_name**() returns NULL and sets *errno* to indicate the error.

ERRORS

See *realpath*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
canonicalize_file_name()	Thread safety	MT-Safe

STANDARDS

NAME

carg, cargf, cargl − calculate the complex argument

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double carg(double complex *z***);**
float cargf(float complex *z***);**
long double cargl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex argument (also called phase angle) of *z*, with a branch cut along the negative real axis.

A complex number can be described by two real coordinates. One may use rectangular coordinates and gets

```
z = x + I * y
```

where *x = creal(z)* and *y = cimag(z)*.

Or one may use polar coordinates and gets

```
z = r * cexp(I * a)
```

where *r = cabs(z)* is the "radius", the "modulus", the absolute value of *z*, and *a = carg(z)* is the "phase angle", the argument of *z*.

One has:

```
tan(carg(z)) = cimag(z) / creal(z)
```

RETURN VALUE

The return value is in the range of [−pi,pi].

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

catgets − get message from a message catalog

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <nl_types.h>

char *catgets(nl_catd *catalog***, int** *set_number***, int** *message_number***,**
const char * *message***);**

DESCRIPTION

catgets() reads the message *message_number*, in set *set_number*, from the message catalog identified by *catalog*, where *catalog* is a catalog descriptor returned from an earlier call to *catopen*(3). The fourth argument, *message*, points to a default message string which will be returned by **catgets**() if the identified message catalog is not currently available. The message-text is contained in an internal buffer area and should be copied by the application if it is to be saved or modified. The return string is always terminated with a null byte ('\0').

RETURN VALUE

On success, **catgets**() returns a pointer to an internal buffer area containing the null-terminated message string. On failure, **catgets**() returns the value *message*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
catgets()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

The **catgets**() function is available only in libc.so.4.4.4c and above.

The Jan 1987 X/Open Portability Guide specifies a more subtle error return: *message* is returned if the message catalog specified by *catalog* is not available, while an empty string is returned when the message catalog is available but does not contain the specified message. These two possible error returns seem to be discarded in SUSv2 in favor of always returning *message*.

SEE ALSO

catopen(3), *setlocale*(3)

NAME

catopen, catclose − open/close a message catalog

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <nl_types.h>

nl_catd catopen(const char *name, int flag);
int catclose(nl_catd catalog);
```

DESCRIPTION

The function **catopen**() opens a message catalog and returns a catalog descriptor. The descriptor remains valid until **catclose**() or *execve*(2). If a file descriptor is used to implement catalog descriptors, then the **FD_CLOEXEC** flag will be set.

The argument *name* specifies the name of the message catalog to be opened. If *name* specifies an absolute path (i.e., contains a '/'), then *name* specifies a pathname for the message catalog. Otherwise, the environment variable **NLSPATH** is used with *name* substituted for **%N** (see *locale*(7)). It is unspecified whether **NLSPATH** will be used when the process has root privileges. If **NLSPATH** does not exist in the environment, or if a message catalog cannot be opened in any of the paths specified by it, then an implementation defined path is used. This latter default path may depend on the **LC_MESSAGES** locale setting when the *flag* argument is **NL_CAT_LOCALE** and on the **LANG** environment variable when the *flag* argument is 0. Changing the **LC_MESSAGES** part of the locale may invalidate open catalog descriptors.

The *flag* argument to **catopen**() is used to indicate the source for the language to use. If it is set to **NL_CAT_LOCALE**, then it will use the current locale setting for **LC_MESSAGES**. Otherwise, it will use the **LANG** environment variable.

The function **catclose**() closes the message catalog identified by *catalog*. It invalidates any subsequent references to the message catalog defined by *catalog*.

RETURN VALUE

The function **catopen**() returns a message catalog descriptor of type *nl_catd* on success. On failure, it returns *(nl_catd) −1* and sets *errno* to indicate the error. The possible error values include all possible values for the *open*(2) call.

The function **catclose**() returns 0 on success, or −1 on failure.

ENVIRONMENT

LC_MESSAGES
: May be the source of the **LC_MESSAGES** locale setting, and thus determine the language to use if *flag* is set to **NL_CAT_LOCALE**.

LANG The language to use if *flag* is 0.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
catopen()	Thread safety	MT-Safe env
catclose()	Thread safety	MT-Safe

VERSIONS

The above is the POSIX.1 description. The glibc value for **NL_CAT_LOCALE** is 1. The default path varies, but usually looks at a number of places below */usr/share/locale*.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

SEE ALSO

NAME

cbrt, cbrtf, cbrtl − cube root function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double cbrt(double x);
float cbrtf(float x);
long double cbrtl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

cbrt():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

cbrtf(), **cbrtl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the (real) cube root of *x*. This function cannot fail; every representable real value has a real cube root, and rounding it to a representable value never causes overflow nor underflow.

RETURN VALUE

These functions return the cube root of *x*.

If *x* is +0, −0, positive infinity, negative infinity, or NaN, *x* is returned.

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

SYNOPSIS

#include <complex.h>

double complex ccosh(double complex *z***);**
float complex ccoshf(float complex *z***);**
long double complex ccoshl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex hyperbolic cosine of *z*.

The complex hyperbolic cosine function is defined as:

```
ccosh(z) = (exp(z)+exp(−z))/2
```

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

SEE ALSO

cabs(3), *cacosh*(3), *csinh*(3), *ctanh*(3), *complex*(7)

NAME

ceil, ceilf, ceill − ceiling function: smallest integral value not less than argument

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double ceil(double x);
float ceilf(float x);
long double ceill(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ceilf(), **ceill**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the smallest integral value that is not less than *x*.

For example, *ceil(0.5)* is 1.0, and *ceil(−0.5)* is 0.0.

RETURN VALUE

These functions return the ceiling of *x*.

If *x* is integral, +0, −0, NaN, or infinite, *x* itself is returned.

ERRORS

No errors occur. POSIX.1-2001 documents a range error for overflows, but see NOTES.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ceil(), **ceilf**(), **ceill**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

NOTES

SUSv2 and POSIX.1-2001 contain text about overflow (which might set *errno* to **ERANGE**, or raise an **FE_OVERFLOW** exception). In practice, the result cannot overflow on any current machine, so this error-handling stuff is just nonsense. (More precisely, overflow can happen only when the maximum value of the exponent is smaller than the number of mantissa bits. For the IEEE-754 standard 32-bit and 64-bit floating-point numbers the maximum value of the exponent is 127 (respectively, 1023), and the number of mantissa bits including the implicit bit is 24 (respectively, 53).)

The integral value returned by these functions may be too large to store in an integer type (*int*, *long*, etc.). To avoid an overflow, which will produce undefined results, an application should perform a range check on the returned value before assigning it to an integer type.

SYNOPSIS

```
#include <complex.h>

double complex cexp2(double complex z);
float complex cexp2f(float complex z);
long double complex cexp2l(long double complex z);
```

DESCRIPTION

The function returns 2 raised to the power of *z*.

STANDARDS

These function names are reserved for future use in C99.

As at glibc 2.31, these functions are not provided in glibc.

SEE ALSO

cabs(3), *cexp*(3), *clog10*(3), *complex*(7)

NAME

cfree − free allocated memory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

/* In SunOS 4 */
int cfree(void ****ptr*);**

/* In glibc or FreeBSD libcompat */
void cfree(void ****ptr*);**

/* In SCO OpenServer */
void cfree(char *ptr***[.***size* *** .***num***], unsigned int** *num***, unsigned int** *size***);**

/* In Solaris watchmalloc.so.1 */
void cfree(void *ptr***[.***elsize* *** .***nelem***], size_t** *nelem***, size_t** *elsize***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

cfree():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

This function should never be used. Use *free*(3) instead. Starting with glibc 2.26, it has been removed from glibc.

1-arg cfree

In glibc, the function **cfree**() is a synonym for *free*(3), "added for compatibility with SunOS".

Other systems have other functions with this name. The declaration is sometimes in <*stdlib.h*> and sometimes in <*malloc.h*>.

3-arg cfree

Some SCO and Solaris versions have malloc libraries with a 3-argument **cfree**(), apparently as an analog to *calloc*(3).

If you need it while porting something, add

```
#define cfree(p, n, s) free((p))
```

to your file.

A frequently asked question is "Can I use *free*(3) to free memory allocated with *calloc*(3), or do I need **cfree**()?" Answer: use *free*(3).

An SCO manual writes: "The cfree routine is provided for compliance to the iBCSe2 standard and simply calls free. The num and size arguments to cfree are not used."

RETURN VALUE

The SunOS version of **cfree**() (which is a synonym for *free*(3)) returns 1 on success and 0 on failure. In case of error, *errno* is set to **EINVAL**: the value of *ptr* was not a pointer to a block previously allocated by one of the routines in the *malloc*(3) family.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cfree()	Thread safety	MT-Safe /* In glibc */

VERSIONS

The 3-argument version of **cfree**() as used by SCO conforms to the iBCSe2 standard: Intel386 Binary Compatibility Specification, Edition 2.

STANDARDS

None.

HISTORY

Removed in glibc 2.26.

NAME

cimag, cimagf, cimagl − get imaginary part of a complex number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double cimag(double complex *z***);**
float cimagf(float complex *z***);**
long double cimagl(long double complex *z***);**

DESCRIPTION

These functions return the imaginary part of the complex number *z*.

One has:

```
z = creal(z) + I * cimag(z)
```

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cimag(), **cimagf**(), **cimagl**()	Thread safety	MT-Safe

VERSIONS

GCC also supports __imag__. That is a GNU extension.

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

CIRCLEQ_FOREACH(struct TYPE ***_var_, CIRCLEQ_HEAD ***_head_**,**
CIRCLEQ_ENTRY *NAME***);**
CIRCLEQ_FOREACH_REVERSE(struct TYPE ***_var_, CIRCLEQ_HEAD ***_head_**,**
CIRCLEQ_ENTRY *NAME***);**

void CIRCLEQ_REMOVE(CIRCLEQ_HEAD ***_head_, struct TYPE ***_elm_**,**
CIRCLEQ_ENTRY *NAME***);**

DESCRIPTION

These macros define and operate on doubly linked circular queues.

In the macro definitions, *TYPE* is the name of a user-defined structure, that must contain a field of type *CIRCLEQ_ENTRY*, named *NAME*. The argument *HEADNAME* is the name of a user-defined structure that must be declared using the macro **CIRCLEQ_HEAD**().

Creation

A circular queue is headed by a structure defined by the **CIRCLEQ_HEAD**() macro. This structure contains a pair of pointers, one to the first element in the queue and the other to the last element in the queue. The elements are doubly linked so that an arbitrary element can be removed without traversing the queue. New elements can be added to the queue after an existing element, before an existing element, at the head of the queue, or at the end of the queue. A *CIRCLEQ_HEAD* structure is declared as follows:

```
CIRCLEQ_HEAD(HEADNAME, TYPE) head;
```

where *struct HEADNAME* is the structure to be defined, and *struct TYPE* is the type of the elements to be linked into the queue. A pointer to the head of the queue can later be declared as:

```
struct HEADNAME *headp;
```

(The names *head* and *headp* are user selectable.)

CIRCLEQ_ENTRY() declares a structure that connects the elements in the queue.

CIRCLEQ_HEAD_INITIALIZER() evaluates to an initializer for the queue *head*.

CIRCLEQ_INIT() initializes the queue referenced by *head*.

CIRCLEQ_EMPTY() evaluates to true if there are no items on the queue.

Insertion

CIRCLEQ_INSERT_HEAD() inserts the new element *elm* at the head of the queue.

CIRCLEQ_INSERT_TAIL() inserts the new element *elm* at the end of the queue.

CIRCLEQ_INSERT_BEFORE() inserts the new element *elm* before the element *listelm*.

CIRCLEQ_INSERT_AFTER() inserts the new element *elm* after the element *listelm*.

Traversal

CIRCLEQ_FIRST() returns the first item on the queue.

CIRCLEQ_LAST() returns the last item on the queue.

CIRCLEQ_PREV() returns the previous item on the queue, or *&head* if this item is the first one.

CIRCLEQ_NEXT() returns the next item on the queue, or *&head* if this item is the last one.

CIRCLEQ_LOOP_PREV() returns the previous item on the queue. If *elm* is the first element on the queue, the last element is returned.

CIRCLEQ_LOOP_NEXT() returns the next item on the queue. If *elm* is the last element on the queue, the first element is returned.

CIRCLEQ_FOREACH() traverses the queue referenced by *head* in the forward direction, assigning each element in turn to *var*. *var* is set to *&head* if the loop completes normally, or if there were no elements.

CIRCLEQ_FOREACH_REVERSE() traverses the queue referenced by *head* in the reverse direction, assigning each element in turn to *var*.

Removal

CIRCLEQ_REMOVE() removes the element *elm* from the queue.

RETURN VALUE

CIRCLEQ_EMPTY() returns nonzero if the queue is empty, and zero if the queue contains at least one entry.

CIRCLEQ_FIRST(), **CIRCLEQ_LAST**(), **CIRCLEQ_LOOP_PREV**(), and **CIRCLEQ_LOOP_NEXT**() return a pointer to the first, last, previous, or next *TYPE* structure, respectively.

CIRCLEQ_PREV(), and **CIRCLEQ_NEXT**() are similar to their **CIRCLEQ_LOOP_***() counterparts, except that if the argument is the first or last element, respectively, they return *&head*.

CIRCLEQ_HEAD_INITIALIZER() returns an initializer that can be assigned to the queue *head*.

STANDARDS

BSD.

BUGS

CIRCLEQ_FOREACH() and **CIRCLEQ_FOREACH_REVERSE**() don't allow *var* to be removed or freed within the loop, as it would interfere with the traversal. **CIRCLEQ_FOREACH_SAFE**() and **CIRCLEQ_FOREACH_REVERSE_SAFE**(), which are present on the BSDs but are not present in glibc, fix this limitation by allowing *var* to safely be removed from the list and freed from within the loop without interfering with the traversal.

EXAMPLES

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/queue.h>
```

```
struct entry {
    int data;
    CIRCLEQ_ENTRY(entry) entries;          /* Queue */
};

CIRCLEQ_HEAD(circlehead, entry);

int
main(void)
{
    struct entry *n1, *n2, *n3, *np;
    struct circlehead head;                /* Queue head */
    int i;

    CIRCLEQ_INIT(&head);                   /* Initialize the queue */

    n1 = malloc(sizeof(struct entry));     /* Insert at the head */
    CIRCLEQ_INSERT_HEAD(&head, n1, entries);

    n1 = malloc(sizeof(struct entry));     /* Insert at the tail */
    CIRCLEQ_INSERT_TAIL(&head, n1, entries);

    n2 = malloc(sizeof(struct entry));     /* Insert after */
    CIRCLEQ_INSERT_AFTER(&head, n1, n2, entries);

    n3 = malloc(sizeof(struct entry));     /* Insert before */
    CIRCLEQ_INSERT_BEFORE(&head, n2, n3, entries);

    CIRCLEQ_REMOVE(&head, n2, entries);    /* Deletion */
    free(n2);
                                           /* Forward traversal */
    i = 0;
    CIRCLEQ_FOREACH(np, &head, entries)
        np->data = i++;
                                           /* Reverse traversal */
    CIRCLEQ_FOREACH_REVERSE(np, &head, entries)
        printf("%i\n", np->data);
                                           /* Queue deletion */
    n1 = CIRCLEQ_FIRST(&head);
    while (n1 != (void *)&head) {
        n2 = CIRCLEQ_NEXT(n1, entries);
        free(n1);
        n1 = n2;
    }
    CIRCLEQ_INIT(&head);

    exit(EXIT_SUCCESS);
}
```

SEE ALSO

insque(3), *queue*(7)

NAME

clearenv − clear the environment

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int clearenv(void);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

clearenv():
/* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

DESCRIPTION

The **clearenv**() function clears the environment of all name-value pairs and sets the value of the external variable *environ* to NULL. After this call, new variables can be added to the environment using *putenv*(3) and *setenv*(3).

RETURN VALUE

The **clearenv**() function returns zero on success, and a nonzero value on failure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
clearenv()	Thread safety	MT-Unsafe const:env

STANDARDS

putenv()
POSIX.1-2008.

clearenv()
None.

HISTORY

putenv()
glibc 2.0. POSIX.1-2001.

clearenv()
glibc 2.0.

Various UNIX variants (DG/UX, HP-UX, QNX, ...). POSIX.9 (bindings for FORTRAN77). POSIX.1-1996 did not accept **clearenv**() and *putenv*(3), but changed its mind and scheduled these functions for some later issue of this standard (see §B.4.6.1). However, POSIX.1-2001 adds only *putenv*(3), and rejected **clearenv**().

NOTES

On systems where **clearenv**() is unavailable, the assignment

```
environ = NULL;
```

will probably do.

The **clearenv**() function may be useful in security-conscious applications that want to precisely control the environment that is passed to programs executed using *exec*(3). The application would do this by first clearing the environment and then adding select environment variables.

Note that the main effect of **clearenv**() is to adjust the value of the pointer *environ*(7); this function does not erase the contents of the buffers containing the environment definitions.

The DG/UX and Tru64 man pages write: If *environ* has been modified by anything other than the *putenv*(3), *getenv*(3), or **clearenv**() functions, then **clearenv**() will return an error and the process environment will remain unchanged.

SEE ALSO

getenv(3), *putenv*(3), *setenv*(3), *unsetenv*(3), *environ*(7)

NAME

clock − determine processor time

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <time.h>

clock_t clock(void);

DESCRIPTION

The **clock**() function returns an approximation of processor time used by the program.

RETURN VALUE

The value returned is the CPU time used so far as a *clock_t*; to get the number of seconds used, divide by **CLOCKS_PER_SEC**. If the processor time used is not available or its value cannot be represented, the function returns the value *(clock_t) −1*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
clock()	Thread safety	MT-Safe

VERSIONS

XSI requires that **CLOCKS_PER_SEC** equals 1000000 independent of the actual resolution.

On several other implementations, the value returned by **clock**() also includes the times of any children whose status has been collected via *wait*(2) (or another wait-type call). Linux does not include the times of waited-for children in the value returned by **clock**(). The *times*(2) function, which explicitly returns (separate) information about the caller and its children, may be preferable.

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89.

In glibc 2.17 and earlier, **clock**() was implemented on top of *times*(2). For improved accuracy, since glibc 2.18, it is implemented on top of *clock_gettime*(2) (using the **CLOCK_PROCESS_CPUTIME_ID** clock).

NOTES

The C standard allows for arbitrary values at the start of the program; subtract the value returned from a call to **clock**() at the start of the program to get maximum portability.

Note that the time can wrap around. On a 32-bit system where **CLOCKS_PER_SEC** equals 1000000 this function will return the same value approximately every 72 minutes.

SEE ALSO

clock_gettime(2), *getrusage*(2), *times*(2)

NAME

clock_getcpuclockid − obtain ID of a process CPU-time clock

LIBRARY

Standard C library (*libc*, *−lc*), since glibc 2.17

Before glibc 2.17, Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <time.h>

int clock_getcpuclockid(pid_t *pid***, clockid_t ****clockid***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

clock_getcpuclockid():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **clock_getcpuclockid**() function obtains the ID of the CPU-time clock of the process whose ID is *pid*, and returns it in the location pointed to by *clockid*. If *pid* is zero, then the clock ID of the CPU-time clock of the calling process is returned.

RETURN VALUE

On success, **clock_getcpuclockid**() returns 0; on error, it returns one of the positive error numbers listed in ERRORS.

ERRORS

ENOSYS
The kernel does not support obtaining the per-process CPU-time clock of another process, and *pid* does not specify the calling process.

EPERM
The caller does not have permission to access the CPU-time clock of the process specified by *pid*. (Specified in POSIX.1-2001; does not occur on Linux unless the kernel does not support obtaining the per-process CPU-time clock of another process.)

ESRCH
There is no process with the ID *pid*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
clock_getcpuclockid()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2. POSIX.1-2001.

NOTES

Calling *clock_gettime*(2) with the clock ID obtained by a call to **clock_getcpuclockid**() with a *pid* of 0, is the same as using the clock ID **CLOCK_PROCESS_CPUTIME_ID**.

EXAMPLES

The example program below obtains the CPU-time clock ID of the process whose ID is given on the command line, and then uses *clock_gettime*(2) to obtain the time on that clock. An example run is the following:

```
$ ./a.out 1                 # Show CPU clock of init process
CPU-time clock for PID 1 is 2.213466748 seconds
```

Program source

```
#define _XOPEN_SOURCE 600
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
```

```
#include <time.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    clockid_t clockid;
    struct timespec ts;

    if (argc != 2) {
        fprintf(stderr, "%s <process-ID>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    if (clock_getcpuclockid(atoi(argv[1]), &clockid) != 0) {
        perror("clock_getcpuclockid");
        exit(EXIT_FAILURE);
    }

    if (clock_gettime(clockid, &ts) == -1) {
        perror("clock_gettime");
        exit(EXIT_FAILURE);
    }

    printf("CPU-time clock for PID %s is %jd.%09ld seconds\n",
           argv[1], (intmax_t) ts.tv_sec, ts.tv_nsec);
    exit(EXIT_SUCCESS);
}
```

NAME

clog, clogf, clogl − natural logarithm of a complex number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex clog(double complex *z***);**
float complex clogf(float complex *z***);**
long double complex clogl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex natural logarithm of *z*, with a branch cut along the negative real axis.

The logarithm **clog**() is the inverse function of the exponential *cexp*(3). Thus, if *y* = *clog(z)*, then *z* = *cexp(y)*. The imaginary part of *y* is chosen in the interval [−pi,pi].

One has:

```
clog(z) = log(cabs(z)) + I * carg(z)
```

Note that *z* close to zero will cause an overflow.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
clog(), **clogf**(), **clogl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

clog10, clog10f, clog10l − base-10 logarithm of a complex number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <complex.h>

double complex clog10(double complex z);
float complex clog10f(float complex z);
long double complex clog10l(long double complex z);
```

DESCRIPTION

The call *clog10(z)* is equivalent to:

```
clog(z)/log(10)
```

or equally:

```
log10(cabs(c)) + I * carg(c) / log(10)
```

The other functions perform the same task for *float* and *long double*.

Note that *z* close to zero will cause an overflow.

NAME

closedir − close a directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <dirent.h>

int closedir(DIR *dirp);
```

DESCRIPTION

The **closedir**() function closes the directory stream associated with *dirp*. A successful call to **closedir**() also closes the underlying file descriptor associated with *dirp*. The directory stream descriptor *dirp* is not available after this call.

RETURN VALUE

The **closedir**() function returns 0 on success. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EBADF
: Invalid directory stream descriptor *dirp*.

ATTRIBUTES

NAME

CMSG_ALIGN, CMSG_SPACE, CMSG_NXTHDR, CMSG_FIRSTHDR − access ancillary data

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/socket.h>

struct cmsghdr *CMSG_FIRSTHDR(struct msghdr **msgh*);
struct cmsghdr *CMSG_NXTHDR(struct msghdr **msgh*,
struct cmsghdr ***cmsg);**
size_t CMSG_ALIGN(size_t *length***);**
size_t CMSG_SPACE(size_t *length***);**
size_t CMSG_LEN(size_t *length***);**
unsigned char *CMSG_DATA(struct cmsghdr **cmsg*);

DESCRIPTION

These macros are used to create and access control messages (also called ancillary data) that are not a part of the socket payload. This control information may include the interface the packet was received on, various rarely used header fields, an extended error description, a set of file descriptors, or UNIX credentials. For instance, control messages can be used to send additional header fields such as IP options. Ancillary data is sent by calling *sendmsg*(2) and received by calling *recvmsg*(2). See their manual pages for more information.

Ancillary data is a sequence of *cmsghdr* structures with appended data. See the specific protocol man pages for the available control message types. The maximum ancillary buffer size allowed per socket can be set using */proc/sys/net/core/optmem_max*; see *socket*(7).

The *cmsghdr* structure is defined as follows:

```
struct cmsghdr {
    size_t cmsg_len;    /* Data byte count, including header
                           (type is socklen_t in POSIX) */
    int    cmsg_level;  /* Originating protocol */
    int    cmsg_type;   /* Protocol-specific type */
/* followed by
   unsigned char cmsg_data[]; */
};
```

The sequence of *cmsghdr* structures should never be accessed directly. Instead, use only the following macros:

CMSG_FIRSTHDR()
: returns a pointer to the first *cmsghdr* in the ancillary data buffer associated with the passed *msghdr*. It returns NULL if there isn't enough space for a *cmsghdr* in the buffer.

CMSG_NXTHDR()
: returns the next valid *cmsghdr* after the passed *cmsghdr*. It returns NULL when there isn't enough space left in the buffer.

  When initializing a buffer that will contain a series of *cmsghdr* structures (e.g., to be sent with *sendmsg*(2)), that buffer should first be zero-initialized to ensure the correct operation of **CMSG_NXTHDR**().

CMSG_ALIGN(),
: given a length, returns it including the required alignment. This is a constant expression.

CMSG_SPACE()
: returns the number of bytes an ancillary element with payload of the passed data length occupies. This is a constant expression.

CMSG_DATA()
: returns a pointer to the data portion of a *cmsghdr*. The pointer returned cannot be assumed to be suitably aligned for accessing arbitrary payload data types. Applications should not cast it to a pointer type matching the payload, but should instead use *memcpy*(3) to copy data to or from a suitably declared object.

CMSG_LEN()
: returns the value to store in the *cmsg_len* member of the *cmsghdr* structure, taking into account any necessary alignment. It takes the data length as an argument. This is a constant expression.

To create ancillary data, first initialize the *msg_controllen* member of the *msghdr* with the length of the control message buffer. Use **CMSG_FIRSTHDR**() on the *msghdr* to get the first control message and **CMSG_NXTHDR**() to get all subsequent ones. In each control message, initialize *cmsg_len* (with *CMSG_LEN*()), the other *cmsghdr* header fields, and the data portion using **CMSG_DATA**(). Finally, the *msg_controllen* field of the *msghdr* should be set to the sum of the **CMSG_SPACE**() of the length of all control messages in the buffer. For more information on the *msghdr*, see *recvmsg*(2).

VERSIONS

For portability, ancillary data should be accessed using only the macros described here.

In Linux, **CMSG_LEN**(), **CMSG_DATA**(), and **CMSG_ALIGN**() are constant expressions (assuming their argument is constant), meaning that these values can be used to declare the size of global variables. This may not be portable, however.

STANDARDS

CMSG_FIRSTHDR()
CMSG_NXTHDR()
CMSG_DATA()
: POSIX.1-2008.

CMSG_SPACE()
CMSG_LEN()
CMSG_ALIGN()
: Linux.

HISTORY

This ancillary data model conforms to the POSIX.1g draft, 4.4BSD-Lite, the IPv6 advanced API described in RFC 2292 and SUSv2.

CMSG_SPACE() and **CMSG_LEN**() will be included in the next POSIX release (Issue 8).

EXAMPLES

This code looks for the **IP_TTL** option in a received ancillary buffer:

```
struct msghdr msgh;
struct cmsghdr *cmsg;
int received_ttl;

/* Receive auxiliary data in msgh */

for (cmsg = CMSG_FIRSTHDR(&msgh); cmsg != NULL;
        cmsg = CMSG_NXTHDR(&msgh, cmsg)) {
    if (cmsg->cmsg_level == IPPROTO_IP
            && cmsg->cmsg_type == IP_TTL) {
        memcpy(&receive_ttl, CMSG_DATA(cmsg), sizeof(received_ttl));
        break;
    }
}

if (cmsg == NULL) {
    /* Error: IP_TTL not enabled or small buffer or I/O error */
}
```

The code below passes an array of file descriptors over a UNIX domain socket using **SCM_RIGHTS**:

```
struct msghdr msg = { 0 };
struct cmsghdr *cmsg;
int myfds[NUM_FD];  /* Contains the file descriptors to pass */
char iobuf[1];
struct iovec io = {
```

```
        .iov_base = iobuf,
        .iov_len = sizeof(iobuf)
    };
    union {         /* Ancillary data buffer, wrapped in a union
                       in order to ensure it is suitably aligned */
        char buf[CMSG_SPACE(sizeof(myfds))];
        struct cmsghdr align;
    } u;

    msg.msg_iov = &io;
    msg.msg_iovlen = 1;
    msg.msg_control = u.buf;
    msg.msg_controllen = sizeof(u.buf);
    cmsg = CMSG_FIRSTHDR(&msg);
    cmsg->cmsg_level = SOL_SOCKET;
    cmsg->cmsg_type = SCM_RIGHTS;
    cmsg->cmsg_len = CMSG_LEN(sizeof(myfds));
    memcpy(CMSG_DATA(cmsg), myfds, sizeof(myfds));
```

For a complete code example that shows passing of file descriptors over a UNIX domain socket, see *seccomp_unotify*(2).

RFC 2292

NAME

confstr − get configuration dependent string variables

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

size_t confstr(int *name***, char** *buf***[.**size**], size_t** *size***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

confstr():
_POSIX_C_SOURCE >= 2 || _XOPEN_SOURCE

DESCRIPTION

confstr() gets the value of configuration-dependent string variables.

The *name* argument is the system variable to be queried. The following variables are supported:

_CS_GNU_LIBC_VERSION (GNU C library only; since glibc 2.3.2)
A string which identifies the GNU C library version on this system (e.g., "glibc 2.3.4").

_CS_GNU_LIBPTHREAD_VERSION (GNU C library only; since glibc 2.3.2)
A string which identifies the POSIX implementation supplied by this C library (e.g., "NPTL 2.3.4" or "linuxthreads−0.10").

_CS_PATH
A value for the **PATH** variable which indicates where all the POSIX.2 standard utilities can be found.

If *buf* is not NULL and *size* is not zero, **confstr**() copies the value of the string to *buf* truncated to *size − 1* bytes if necessary, with a null byte ('\0') as terminator. This can be detected by comparing the return value of **confstr**() against *size*.

If *size* is zero and *buf* is NULL, **confstr**() just returns the value as defined below.

RETURN VALUE

If *name* is a valid configuration variable, **confstr**() returns the number of bytes (including the terminating null byte) that would be required to hold the entire value of that variable. This value may be greater than *size*, which means that the value in *buf* is truncated.

If *name* is a valid configuration variable, but that variable does not have a value, then **confstr**() returns 0. If *name* does not correspond to a valid configuration variable, **confstr**() returns 0, and *errno* is set to **EINVAL**.

ERRORS

EINVAL
The value of *name* is invalid.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
confstr()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

The following code fragment determines the path where to find the POSIX.2 system utilities:

```
char *pathbuf;
size_t n;

n = confstr(_CS_PATH, NULL, (size_t) 0);
pathbuf = malloc(n);
```

```
        if (pathbuf == NULL)
            abort();
        confstr(_CS_PATH, pathbuf, n);
```

SEE ALSO

getconf(1), *sh*(1), *exec*(3), *fpathconf*(3), *pathconf*(3), *sysconf*(3), *system*(3)

NAME

conj, conjf, conjl − calculate the complex conjugate

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex conj(double complex *z***);**
float complex conjf(float complex *z***);**
long double complex conjl(long double complex *z***);**

DESCRIPTION

These functions return the complex conjugate value of *z*. That is the value obtained by changing the sign of the imaginary part.

One has:

```
cabs(z) = csqrt(z * conj(z))
```

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
conj(), **conjf**(), **conjl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

SEE ALSO

cabs(3), *csqrt*(3), *complex*(7)

NAME

copysign, copysignf, copysignl − copy sign of a number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double copysign(double x, double y);
float copysignf(float x, float y);
long double copysignl(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

copysign(), **copysignf**(), **copysignl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return a value whose absolute value matches that of *x*, but whose sign bit matches that of *y*.

For example, *copysign(42.0, −1.0)* and *copysign(−42.0, −1.0)* both return −42.0.

RETURN VALUE

On success, these functions return a value whose magnitude is taken from *x* and whose sign is taken from *y*.

If *x* is a NaN, a NaN with the sign bit of *y* is returned.

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
copysign(), **copysignf**(), **copysignl**()	Thread safety	MT-Safe

VERSIONS

On architectures where the floating-point formats are not IEEE 754 compliant, these functions may treat a negative zero as positive.

STANDARDS

C11, POSIX.1-2008.

This function is defined in IEC 559 (and the appendix with recommended functions in IEEE 754/IEEE 854).

HISTORY

C99, POSIX.1-2001, 4.3BSD.

SEE ALSO

signbit(3)

NAME

cos, cosf, cosl − cosine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double cos(double x);
float cosf(float x);
long double cosl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

cosf(), **cosl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the cosine of *x*, where *x* is given in radians.

RETURN VALUE

On success, these functions return the cosine of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity or negative infinity, a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cos(), **cosf**(), **cosl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD.

BUGS

Before glibc 2.10, the glibc implementation did not set *errno* to **EDOM** when a domain error occurred.

NAME

cosh, coshf, coshl − hyperbolic cosine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <math.h>

double cosh(double *x***);**
float coshf(float *x***);**
long double coshl(long double *x***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

coshf(), **coshl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the hyperbolic cosine of *x*, which is defined mathematically as:

```
cosh(x) = (exp(x) + exp(−x)) / 2
```

RETURN VALUE

On success, these functions return the hyperbolic cosine of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is +0 or −0, 1 is returned.

If *x* is positive infinity or negative infinity, positive infinity is returned.

If the result overflows, a range error occurs, and the functions return +**HUGE_VAL**, +**HUGE_VALF**, or +**HUGE_VALL**, respectively.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cosh(), **coshf**(), **coshl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD.

BUGS

In glibc 2.3.4 and earlier, an overflow floating-point (**FE_OVERFLOW**) exception is not raised when an overflow occurs.

NAME

cproj, cprojf, cprojl − project into Riemann Sphere

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex cproj(double complex *z***);**
float complex cprojf(float complex *z***);**
long double complex cprojl(long double complex *z***);**

DESCRIPTION

These functions project a point in the plane onto the surface of a Riemann Sphere, the one-point compactification of the complex plane. Each finite point *z* projects to *z* itself. Every complex infinite value is projected to a single infinite value, namely to positive infinity on the real axis.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
cproj(), **cprojf**(), **cprojl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

In glibc 2.11 and earlier, the implementation does something different (a *stereographic* projection onto a Riemann Sphere).

        cpu_set_t *srcset1, cpu_set_t *srcset2);

int  CPU_EQUAL_S(size_t setsize, cpu_set_t *set1, cpu_set_t *set2);
```

DESCRIPTION

The *cpu_set_t* data structure represents a set of CPUs. CPU sets are used by *sched_setaffinity*(2) and similar interfaces.

The *cpu_set_t* data type is implemented as a bit mask. However, the data structure should be treated as opaque: all manipulation of CPU sets should be done via the macros described in this page.

The following macros are provided to operate on the CPU set *set*:

CPU_ZERO()
: Clears *set*, so that it contains no CPUs.

CPU_SET()
: Add CPU *cpu* to *set*.

CPU_CLR()
: Remove CPU *cpu* from *set*.

CPU_ISSET()
Test to see if CPU *cpu* is a member of *set*.

CPU_COUNT()
Return the number of CPUs in *set*.

Where a *cpu* argument is specified, it should not produce side effects, since the above macros may evaluate the argument more than once.

The first CPU on the system corresponds to a *cpu* value of 0, the next CPU corresponds to a *cpu* value of 1, and so on. No assumptions should be made about particular CPUs being available, or the set of CPUs being contiguous, since CPUs can be taken offline dynamically or be otherwise absent. The constant **CPU_SETSIZE** (currently 1024) specifies a value one greater than the maximum CPU number that can be stored in *cpu_set_t*.

The following macros perform logical operations on CPU sets:

CPU_AND()
Store the intersection of the sets *srcset1* and *srcset2* in *destset* (which may be one of the source sets).

CPU_OR()
Store the union of the sets *srcset1* and *srcset2* in *destset* (which may be one of the source sets).

CPU_XOR()
Store the XOR of the sets *srcset1* and *srcset2* in *destset* (which may be one of the source sets). The XOR means the set of CPUs that are in either *srcset1* or *srcset2*, but not both.

CPU_EQUAL()
Test whether two CPU set contain exactly the same CPUs.

Dynamically sized CPU sets

Because some applications may require the ability to dynamically size CPU sets (e.g., to allocate sets larger than that defined by the standard *cpu_set_t* data type), glibc nowadays provides a set of macros to support this.

The following macros are used to allocate and deallocate CPU sets:

CPU_ALLOC()
Allocate a CPU set large enough to hold CPUs in the range 0 to *num_cpus−1*.

CPU_ALLOC_SIZE()
Return the size in bytes of the CPU set that would be needed to hold CPUs in the range 0 to *num_cpus−1*. This macro provides the value that can be used for the *setsize* argument in the **CPU_*_S**() macros described below.

CPU_FREE()
Free a CPU set previously allocated by **CPU_ALLOC**().

The macros whose names end with "_S" are the analogs of the similarly named macros without the suffix. These macros perform the same tasks as their analogs, but operate on the dynamically allocated CPU set(s) whose size is *setsize* bytes.

RETURN VALUE

CPU_ISSET() and **CPU_ISSET_S**() return nonzero if *cpu* is in *set*; otherwise, it returns 0.

CPU_COUNT() and **CPU_COUNT_S**() return the number of CPUs in *set*.

CPU_EQUAL() and **CPU_EQUAL_S**() return nonzero if the two CPU sets are equal; otherwise they return 0.

CPU_ALLOC() returns a pointer on success, or NULL on failure. (Errors are as for *malloc*(3).)

CPU_ALLOC_SIZE() returns the number of bytes required to store a CPU set of the specified cardinality.

The other functions do not return a value.

STANDARDS

Linux.

HISTORY

The **CPU_ZERO**(), **CPU_SET**(), **CPU_CLR**(), and **CPU_ISSET**() macros were added in glibc 2.3.3.

CPU_COUNT() first appeared in glibc 2.6.

CPU_AND(), **CPU_OR**(), **CPU_XOR**(), **CPU_EQUAL**(), **CPU_ALLOC**(), **CPU_ALLOC_SIZE**(), **CPU_FREE**(), **CPU_ZERO_S**(), **CPU_SET_S**(), **CPU_CLR_S**(), **CPU_ISSET_S**(), **CPU_AND_S**(), **CPU_OR_S**(), **CPU_XOR_S**(), and **CPU_EQUAL_S**() first appeared in glibc 2.7.

NOTES

To duplicate a CPU set, use *memcpy*(3).

Since CPU sets are bit masks allocated in units of long words, the actual number of CPUs in a dynamically allocated CPU set will be rounded up to the next multiple of *sizeof(unsigned long)*. An application should consider the contents of these extra bits to be undefined.

Notwithstanding the similarity in the names, note that the constant **CPU_SETSIZE** indicates the number of CPUs in the *cpu_set_t* data type (thus, it is effectively a count of the bits in the bit mask), while the *setsize* argument of the **CPU_*_S**() macros is a size in bytes.

The data types for arguments and return values shown in the SYNOPSIS are hints what about is expected in each case. However, since these interfaces are implemented as macros, the compiler won't necessarily catch all type errors if you violate the suggestions.

BUGS

On 32-bit platforms with glibc 2.8 and earlier, **CPU_ALLOC**() allocates twice as much space as is required, and **CPU_ALLOC_SIZE**() returns a value twice as large as it should. This bug should not affect the semantics of a program, but does result in wasted memory and less efficient operation of the macros that operate on dynamically allocated CPU sets. These bugs are fixed in glibc 2.9.

EXAMPLES

The following program demonstrates the use of some of the macros used for dynamically allocated CPU sets.

```
#define _GNU_SOURCE
#include <sched.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

#include <assert.h>

int
main(int argc, char *argv[])
{
    cpu_set_t *cpusetp;
    size_t size, num_cpus;

    if (argc < 2) {
        fprintf(stderr, "Usage: %s <num-cpus>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    num_cpus = atoi(argv[1]);

    cpusetp = CPU_ALLOC(num_cpus);
    if (cpusetp == NULL) {
        perror("CPU_ALLOC");
        exit(EXIT_FAILURE);
    }

    size = CPU_ALLOC_SIZE(num_cpus);
```

```
        CPU_ZERO_S(size, cpusetp);
        for (size_t cpu = 0; cpu < num_cpus; cpu += 2)
            CPU_SET_S(cpu, size, cpusetp);

        printf("CPU_COUNT() of set:    %d\n", CPU_COUNT_S(size, cpusetp));

        CPU_FREE(cpusetp);
        exit(EXIT_SUCCESS);
    }
```

NAME

crypt, crypt_r − password hashing

LIBRARY

Password hashing library (*libcrypt*, *−lcrypt*)

SYNOPSIS

#include <unistd.h>

char *crypt(const char *_key_, const char *_salt_);

#include <crypt.h>

char *crypt_r(const char *_key_, const char *_salt_,
struct crypt_data *restrict *data*);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

crypt():
Since glibc 2.28:
_DEFAULT_SOURCE
glibc 2.27 and earlier:
_XOPEN_SOURCE

crypt_r():
_GNU_SOURCE

DESCRIPTION

crypt() is the password hashing function. It is based on the Data Encryption Standard algorithm with variations intended (among other things) to discourage use of hardware implementations of a key search.

key is a user's typed password.

salt is a two-character string chosen from the set [**a−zA−Z0−9./**]. This string is used to perturb the algorithm in one of 4096 different ways.

By taking the lowest 7 bits of each of the first eight characters of the *key*, a 56-bit key is obtained. This 56-bit key is used to encrypt repeatedly a constant string (usually a string consisting of all zeros). The returned value points to the hashed password, a series of 13 printable ASCII characters (the first two characters represent the salt itself). The return value points to static data whose content is overwritten by each call.

Warning: the key space consists of 2^{56} equal 7.2e16 possible values. Exhaustive searches of this key space are possible using massively parallel computers. Software, such as *crack*(1), is available which will search the portion of this key space that is generally used by humans for passwords. Hence, password selection should, at minimum, avoid common words and names. The use of a *passwd*(1) program that checks for crackable passwords during the selection process is recommended.

The DES algorithm itself has a few quirks which make the use of the **crypt**() interface a very poor choice for anything other than password authentication. If you are planning on using the **crypt**() interface for a cryptography project, don't do it: get a good book on encryption and one of the widely available DES libraries.

crypt_r() is a reentrant version of **crypt**(). The structure pointed to by *data* is used to store result data and bookkeeping information. Other than allocating it, the only thing that the caller should do with this structure is to set *data−>initialized* to zero before the first call to **crypt_r**().

RETURN VALUE

On success, a pointer to the hashed password is returned. On error, NULL is returned.

ERRORS

EINVAL
salt has the wrong format.

ENOSYS
The **crypt**() function was not implemented, probably because of U.S.A. export restrictions.

EPERM
/proc/sys/crypto/fips_enabled has a nonzero value, and an attempt was made to use a weak hashing type, such as DES.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
crypt()	Thread safety	MT-Unsafe race:crypt
crypt_r()	Thread safety	MT-Safe

STANDARDS

crypt() POSIX.1-2008.

crypt_r()
GNU.

HISTORY

crypt() POSIX.1-2001, SVr4, 4.3BSD.

Availability in glibc

The **crypt**(), *encrypt*(3), and *setkey*(3) functions are part of the POSIX.1-2008 XSI Options Group for Encryption and are optional. If the interfaces are not available, then the symbolic constant **_XOPEN_CRYPT** is either not defined, or it is defined to −1 and availability can be checked at run time with *sysconf*(3). This may be the case if the downstream distribution has switched from glibc crypt to *libxcrypt*. When recompiling applications in such distributions, the programmer must detect if **_XOPEN_CRYPT** is not available and include <*crypt.h*> for the function prototypes; otherwise *libxcrypt* is an ABI-compatible drop-in replacement.

NOTES

Features in glibc

The glibc version of this function supports additional hashing algorithms.

If *salt* is a character string starting with the characters "$*id*$" followed by a string optionally terminated by "$", then the result has the form:

$*id*$*salt*$*hashed*

id identifies the hashing method used instead of DES and this then determines how the rest of the password string is interpreted. The following values of *id* are supported:

ID	Method
1	MD5
2a	Blowfish (not in mainline glibc; added in some Linux distributions)
5	SHA-256 (since glibc 2.7)
6	SHA-512 (since glibc 2.7)

Thus, 5*salt*$*hashed* and 6*salt*$*hashed* contain the password hashed with, respectively, functions based on SHA-256 and SHA-512.

"*salt*" stands for the up to 16 characters following "$*id*$" in the salt. The "*hashed*" part of the password string is the actual computed password. The size of this string is fixed:

MD5 22 characters
SHA-256 43 characters
SHA-512 86 characters

The characters in "*salt*" and "*hashed*" are drawn from the set [**a−zA−Z0−9./**]. In the MD5 and SHA implementations the entire *key* is significant (instead of only the first 8 bytes in DES).

Since glibc 2.7, the SHA-256 and SHA-512 implementations support a user-supplied number of hashing rounds, defaulting to 5000. If the "$*id*$" characters in the salt are followed by "rounds=*xxx*$", where *xxx* is an integer, then the result has the form

$*id*$*rounds=yyy*$*salt*$*hashed*

where *yyy* is the number of hashing rounds actually used. The number of rounds actually used is 1000 if *xxx* is less than 1000, 999999999 if *xxx* is greater than 999999999, and is equal to *xxx* otherwise.

NAME

csinh, csinhf, csinhl − complex hyperbolic sine

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex csinh(double complex *z***);**
float complex csinhf(float complex *z***);**
long double complex csinhl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex hyperbolic sine of *z*.

The complex hyperbolic sine function is defined as:

```
csinh(z) = (exp(z)−exp(−z))/2
```

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

csqrt, csqrtf, csqrtl − complex square root

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <complex.h>

double complex csqrt(double complex *z***);**
float complex csqrtf(float complex *z***);**
long double complex csqrtl(long double complex *z***);**

DESCRIPTION

These functions calculate the complex square root of *z*, with a branch cut along the negative real axis. (That means that *csqrt(−1+eps*I)* will be close to I while *csqrt(−1−eps*I)* will be close to −I, *if eps* is a small positive real number.)

NAME

ctermid − get controlling terminal name

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

char *ctermid(char ****s*);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ctermid():
_POSIX_C_SOURCE

DESCRIPTION

ctermid() returns a string which is the pathname for the current controlling terminal for this process. If *s* is NULL, a static buffer is used, otherwise *s* points to a buffer used to hold the terminal pathname. The symbolic constant **L_ctermid** is the maximum number of characters in the returned pathname.

RETURN VALUE

The pointer to the pathname.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ctermid()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, Svr4.

BUGS

The returned pathname may not uniquely identify the controlling terminal; it may, for example, be */dev/tty*.

It is not assured that the program can open the terminal.

SEE ALSO

ttyname(3)

NAME

asctime, ctime, gmtime, localtime, mktime, asctime_r, ctime_r, gmtime_r, localtime_r − transform date and time to broken-down time or ASCII

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <time.h>

char *asctime(const struct tm *tm);
char *asctime_r(const struct tm *restrict tm,
                char buf[restrict 26]);

char *ctime(const time_t *timep);
char *ctime_r(const time_t *restrict timep,
                char buf[restrict 26]);

struct tm *gmtime(const time_t *timep);
struct tm *gmtime_r(const time_t *restrict timep,
                struct tm *restrict result);

struct tm *localtime(const time_t *timep);
struct tm *localtime_r(const time_t *restrict timep,
                struct tm *restrict result);

time_t mktime(struct tm *tm);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

asctime_r(), **ctime_r**(), **gmtime_r**(), **localtime_r**():
_POSIX_C_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **ctime**(), **gmtime**(), and **localtime**() functions all take an argument of data type *time_t*, which represents calendar time. When interpreted as an absolute time value, it represents the number of seconds elapsed since the Epoch, 1970-01-01 00:00:00 +0000 (UTC).

The **asctime**() and **mktime**() functions both take an argument representing broken-down time, which is a representation separated into year, month, day, and so on.

Broken-down time is stored in the structure *tm*, described in *tm*(3type).

The call **ctime(*t*)** is equivalent to **asctime(localtime(*t*))**. It converts the calendar time *t* into a null-terminated string of the form

```
"Wed Jun 30 21:49:08 1993\n"
```

The abbreviations for the days of the week are "Sun", "Mon", "Tue", "Wed", "Thu", "Fri", and "Sat". The abbreviations for the months are "Jan", "Feb", "Mar", "Apr", "May", "Jun", "Jul", "Aug", "Sep", "Oct", "Nov", and "Dec". The return value points to a statically allocated string which might be overwritten by subsequent calls to any of the date and time functions. The function also sets the external variables *tzname*, *timezone*, and *daylight* (see *tzset*(3)) with information about the current timezone. The reentrant version **ctime_r**() does the same, but stores the string in a user-supplied buffer which should have room for at least 26 bytes. It need not set *tzname*, *timezone*, and *daylight*.

The **gmtime**() function converts the calendar time *timep* to broken-down time representation, expressed in Coordinated Universal Time (UTC). It may return NULL when the year does not fit into an integer. The return value points to a statically allocated struct which might be overwritten by subsequent calls to any of the date and time functions. The **gmtime_r**() function does the same, but stores the data in a user-supplied struct.

The **localtime**() function converts the calendar time *timep* to broken-down time representation, expressed relative to the user's specified timezone. The function acts as if it called *tzset*(3) and sets the external variables *tzname* with information about the current timezone, *timezone* with the difference between Coordinated Universal Time (UTC) and local standard time in seconds, and *daylight* to a nonzero value if daylight savings time rules apply during some part of the year. The return value points to a statically allocated struct which might be overwritten by subsequent calls to any of the date and

time functions. The **localtime_r**() function does the same, but stores the data in a user-supplied struct. It need not set *tzname*, *timezone*, and *daylight*.

The **asctime**() function converts the broken-down time value *tm* into a null-terminated string with the same format as **ctime**(). The return value points to a statically allocated string which might be overwritten by subsequent calls to any of the date and time functions. The **asctime_r**() function does the same, but stores the string in a user-supplied buffer which should have room for at least 26 bytes.

The **mktime**() function converts a broken-down time structure, expressed as local time, to calendar time representation. The function ignores the values supplied by the caller in the *tm_wday* and *tm_yday* fields. The value specified in the *tm_isdst* field informs **mktime**() whether or not daylight saving time (DST) is in effect for the time supplied in the *tm* structure: a positive value means DST is in effect; zero means that DST is not in effect; and a negative value means that **mktime**() should (use timezone information and system databases to) attempt to determine whether DST is in effect at the specified time.

The **mktime**() function modifies the fields of the *tm* structure as follows: *tm_wday* and *tm_yday* are set to values determined from the contents of the other fields; if structure members are outside their valid interval, they will be normalized (so that, for example, 40 October is changed into 9 November); *tm_isdst* is set (regardless of its initial value) to a positive value or to 0, respectively, to indicate whether DST is or is not in effect at the specified time. Calling **mktime**() also sets the external variable *tzname* with information about the current timezone.

If the specified broken-down time cannot be represented as calendar time (seconds since the Epoch), **mktime**() returns *(time_t) −1* and does not alter the members of the broken-down time structure.

RETURN VALUE

On success, **gmtime**() and **localtime**() return a pointer to a *struct tm*.

On success, **gmtime_r**() and **localtime_r**() return the address of the structure pointed to by *result*.

On success, **asctime**() and **ctime**() return a pointer to a string.

On success, **asctime_r**() and **ctime_r**() return a pointer to the string pointed to by *buf*.

On success, **mktime**() returns the calendar time (seconds since the Epoch), expressed as a value of type *time_t*.

On error, **mktime**() returns the value *(time_t) −1*. The remaining functions return NULL on error. On error, *errno* is set to indicate the error.

ERRORS

EOVERFLOW
The result cannot be represented.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
asctime()	Thread safety	MT-Unsafe race:asctime locale
asctime_r()	Thread safety	MT-Safe locale
ctime()	Thread safety	MT-Unsafe race:tmbuf race:asctime env locale
ctime_r(), **gmtime_r**(), **localtime_r**(), **mktime**()	Thread safety	MT-Safe env locale
gmtime(), **localtime**()	Thread safety	MT-Unsafe race:tmbuf env locale

VERSIONS

POSIX doesn't specify the parameters of **ctime_r**() to be *restrict*; that is specific to glibc.

In many implementations, including glibc, a 0 in *tm_mday* is interpreted as meaning the last day of the preceding month.

According to POSIX.1-2001, **localtime**() is required to behave as though *tzset*(3) was called, while **localtime_r**() does not have this requirement. For portable code, *tzset*(3) should be called before **localtime_r**().

STANDARDS

asctime()
ctime()
gmtime()
localtime()
mktime()
C11, POSIX.1-2008.

asctime_r()
ctime_r()
gmtime_r()
localtime_r()
POSIX.1-2008.

HISTORY

gmtime()
localtime()
mktime()
C89, POSIX.1-2001.

asctime()
ctime() C89, POSIX.1-2001. Marked obsolete in POSIX.1-2008 (recommending *strftime*(3)).

gmtime_r()
localtime_r()
POSIX.1-2001.

asctime_r()
ctime_r()
POSIX.1-2001. Marked obsolete in POSIX.1-2008 (recommending *strftime*(3)).

NOTES

The four functions **asctime**(), **ctime**(), **gmtime**(), and **localtime**() return a pointer to static data and hence are not thread-safe. The thread-safe versions, **asctime_r**(), **ctime_r**(), **gmtime_r**(), and **localtime_r**(), are specified by SUSv2.

POSIX.1-2001 says: "The **asctime**(), **ctime**(), **gmtime**(), and **localtime**() functions shall return values in one of two static objects: a broken-down time structure and an array of type *char*. Execution of any of the functions may overwrite the information returned in either of these objects by any of the other functions." This can occur in the glibc implementation.

NAME

daemon − run in the background

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int daemon(int *nochdir***, int** *noclose***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

daemon():
Since glibc 2.21:
_DEFAULT_SOURCE
In glibc 2.19 and 2.20:
_DEFAULT_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)
Up to and including glibc 2.19:
_BSD_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)

DESCRIPTION

The **daemon**() function is for programs wishing to detach themselves from the controlling terminal and run in the background as system daemons.

If *nochdir* is zero, **daemon**() changes the process's current working directory to the root directory ("/"); otherwise, the current working directory is left unchanged.

If *noclose* is zero, **daemon**() redirects standard input, standard output, and standard error to */dev/null*; otherwise, no changes are made to these file descriptors.

RETURN VALUE

(This function forks, and if the *fork*(2) succeeds, the parent calls *_exit*(2), so that further errors are seen by the child only.) On success **daemon**() returns zero. If an error occurs, **daemon**() returns −1 and sets *errno* to any of the errors specified for the *fork*(2) and *setsid*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
daemon()	Thread safety	MT-Safe

VERSIONS

A similar function appears on the BSDs.

The glibc implementation can also return −1 when */dev/null* exists but is not a character device with the expected major and minor numbers. In this case, *errno* need not be set.

STANDARDS

None.

HISTORY

4.4BSD.

BUGS

The GNU C library implementation of this function was taken from BSD, and does not employ the double-fork technique (i.e., *fork*(2), *setsid*(2), *fork*(2)) that is necessary to ensure that the resulting daemon process is not a session leader. Instead, the resulting daemon *is* a session leader. On systems that follow System V semantics (e.g., Linux), this means that if the daemon opens a terminal that is not already a controlling terminal for another session, then that terminal will inadvertently become the controlling terminal for the daemon.

fork(2), *setsid*(2), *daemon*(7), *logrotate*(8)

NAME

dbopen − database access methods

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/types.h>
#include <limits.h>
#include <db.h>
#include <fcntl.h>

DB *dbopen(const char * *file***, int** *flags***, int** *mode***, DBTYPE** *type***,**
const void ***openinfo*);**

DESCRIPTION

Note well: This page documents interfaces provided up until glibc 2.1. Since glibc 2.2, glibc no longer provides these interfaces. Probably, you are looking for the APIs provided by the *libdb* library instead.

dbopen() is the library interface to database files. The supported file formats are btree, hashed, and UNIX file oriented. The btree format is a representation of a sorted, balanced tree structure. The hashed format is an extensible, dynamic hashing scheme. The flat-file format is a byte stream file with fixed or variable length records. The formats and file-format-specific information are described in detail in their respective manual pages *btree*(3), *hash*(3), and *recno*(3).

dbopen() opens *file* for reading and/or writing. Files never intended to be preserved on disk may be created by setting the *file* argument to NULL.

The *flags* and *mode* arguments are as specified to the *open*(2) routine, however, only the **O_CREAT**, **O_EXCL**, **O_EXLOCK**, **O_NONBLOCK**, **O_RDONLY**, **O_RDWR**, **O_SHLOCK**, and **O_TRUNC** flags are meaningful. (Note, opening a database file **O_WRONLY** is not possible.)

The *type* argument is of type *DBTYPE* (as defined in the <*db.h*> include file) and may be set to **DB_BTREE**, **DB_HASH**, or **DB_RECNO**.

The *openinfo* argument is a pointer to an access-method-specific structure described in the access method's manual page. If *openinfo* is NULL, each access method will use defaults appropriate for the system and the access method.

dbopen() returns a pointer to a *DB* structure on success and NULL on error. The *DB* structure is defined in the <*db.h*> include file, and contains at least the following fields:

```
typedef struct {
    DBTYPE type;
    int (*close)(const DB *db);
    int (*del)(const DB *db, const DBT *key, unsigned int flags);
    int (*fd)(const DB *db);
    int (*get)(const DB *db, DBT *key, DBT *data,
               unsigned int flags);
    int (*put)(const DB *db, DBT *key, const DBT *data,
               unsigned int flags);
    int (*sync)(const DB *db, unsigned int flags);
    int (*seq)(const DB *db, DBT *key, DBT *data,
               unsigned int flags);
} DB;
```

These elements describe a database type and a set of functions performing various actions. These functions take a pointer to a structure as returned by **dbopen**(), and sometimes one or more pointers to key/data structures and a flag value.

type The type of the underlying access method (and file format).

close A pointer to a routine to flush any cached information to disk, free any allocated resources, and close the underlying file(s). Since key/data pairs may be cached in memory, failing to sync the file with a *close* or *sync* function may result in inconsistent or lost information. *close* routines return −1 on error (setting *errno*) and 0 on success.

del A pointer to a routine to remove key/data pairs from the database.

The argument *flag* may be set to the following value:

R_CURSOR
Delete the record referenced by the cursor. The cursor must have previously been initialized.

delete routines return −1 on error (setting *errno*), 0 on success, and 1 if the specified *key* was not in the file.

fd A pointer to a routine which returns a file descriptor representative of the underlying database. A file descriptor referencing the same file will be returned to all processes which call **dbopen**() with the same *file* name. This file descriptor may be safely used as an argument to the *fcntl*(2) and *flock*(2) locking functions. The file descriptor is not necessarily associated with any of the underlying files used by the access method. No file descriptor is available for in memory databases. *fd* routines return −1 on error (setting *errno*), and the file descriptor on success.

get A pointer to a routine which is the interface for keyed retrieval from the database. The address and length of the data associated with the specified *key* are returned in the structure referenced by *data*. *get* routines return −1 on error (setting *errno*), 0 on success, and 1 if the *key* was not in the file.

put A pointer to a routine to store key/data pairs in the database.

The argument *flag* may be set to one of the following values:

R_CURSOR
Replace the key/data pair referenced by the cursor. The cursor must have previously been initialized.

R_IAFTER
Append the data immediately after the data referenced by *key*, creating a new key/data pair. The record number of the appended key/data pair is returned in the *key* structure. (Applicable only to the **DB_RECNO** access method.)

R_IBEFORE
Insert the data immediately before the data referenced by *key*, creating a new key/data pair. The record number of the inserted key/data pair is returned in the *key* structure. (Applicable only to the **DB_RECNO** access method.)

R_NOOVERWRITE
Enter the new key/data pair only if the key does not previously exist.

R_SETCURSOR
Store the key/data pair, setting or initializing the position of the cursor to reference it. (Applicable only to the **DB_BTREE** and **DB_RECNO** access methods.)

R_SETCURSOR is available only for the **DB_BTREE** and **DB_RECNO** access methods because it implies that the keys have an inherent order which does not change.

R_IAFTER and **R_IBEFORE** are available only for the **DB_RECNO** access method because they each imply that the access method is able to create new keys. This is true only if the keys are ordered and independent, record numbers for example.

The default behavior of the *put* routines is to enter the new key/data pair, replacing any previously existing key.

put routines return −1 on error (setting *errno*), 0 on success, and 1 if the **R_NOOVERWRITE** *flag* was set and the key already exists in the file.

seq A pointer to a routine which is the interface for sequential retrieval from the database. The address and length of the key are returned in the structure referenced by *key*, and the address and length of the data are returned in the structure referenced by *data*.

Sequential key/data pair retrieval may begin at any time, and the position of the "cursor" is not affected by calls to the *del*, *get*, *put*, or *sync* routines. Modifications to the database during a sequential scan will be reflected in the scan, that is, records inserted behind the cursor will not

be returned while records inserted in front of the cursor will be returned.

The flag value **must** be set to one of the following values:

R_CURSOR
The data associated with the specified key is returned. This differs from the *get* routines in that it sets or initializes the cursor to the location of the key as well. (Note, for the **DB_BTREE** access method, the returned key is not necessarily an exact match for the specified key. The returned key is the smallest key greater than or equal to the specified key, permitting partial key matches and range searches.)

R_FIRST
The first key/data pair of the database is returned, and the cursor is set or initialized to reference it.

R_LAST
The last key/data pair of the database is returned, and the cursor is set or initialized to reference it. (Applicable only to the **DB_BTREE** and **DB_RECNO** access methods.)

R_NEXT
Retrieve the key/data pair immediately after the cursor. If the cursor is not yet set, this is the same as the **R_FIRST** flag.

R_PREV
Retrieve the key/data pair immediately before the cursor. If the cursor is not yet set, this is the same as the **R_LAST** flag. (Applicable only to the **DB_BTREE** and **DB_RECNO** access methods.)

R_LAST and **R_PREV** are available only for the **DB_BTREE** and **DB_RECNO** access methods because they each imply that the keys have an inherent order which does not change.

seq routines return −1 on error (setting *errno*), 0 on success and 1 if there are no key/data pairs less than or greater than the specified or current key. If the **DB_RECNO** access method is being used, and if the database file is a character special file and no complete key/data pairs are currently available, the *seq* routines return 2.

sync A pointer to a routine to flush any cached information to disk. If the database is in memory only, the *sync* routine has no effect and will always succeed.

The flag value may be set to the following value:

R_RECNOSYNC
If the **DB_RECNO** access method is being used, this flag causes the sync routine to apply to the btree file which underlies the recno file, not the recno file itself. (See the *bfname* field of the *recno*(3) manual page for more information.)

sync routines return −1 on error (setting *errno*) and 0 on success.

Key/data pairs

Access to all file types is based on key/data pairs. Both keys and data are represented by the following data structure:

```
typedef struct {
    void  *data;
    size_t size;
} DBT;
```

The elements of the *DBT* structure are defined as follows:

data A pointer to a byte string.

size The length of the byte string.

Key and data byte strings may reference strings of essentially unlimited length although any two of them must fit into available memory at the same time. It should be noted that the access methods provide no guarantees about byte string alignment.

ERRORS

The **dbopen**() routine may fail and set *errno* for any of the errors specified for the library routines *open*(2) and *malloc*(3) or the following:

EFTYPE
A file is incorrectly formatted.

EINVAL
A parameter has been specified (hash function, pad byte, etc.) that is incompatible with the current file specification or which is not meaningful for the function (for example, use of the cursor without prior initialization) or there is a mismatch between the version number of file and the software.

The *close* routines may fail and set *errno* for any of the errors specified for the library routines *close*(2), *read*(2), *write*(2), *free*(3), or *fsync*(2).

The *del*, *get*, *put*, and *seq* routines may fail and set *errno* for any of the errors specified for the library routines *read*(2), *write*(2), *free*(3), or *malloc*(3).

The *fd* routines will fail and set *errno* to **ENOENT** for in memory databases.

The *sync* routines may fail and set *errno* for any of the errors specified for the library routine *fsync*(2).

BUGS

The typedef *DBT* is a mnemonic for "data base thang", and was used because no one could think of a reasonable name that wasn't already used.

The file descriptor interface is a kludge and will be deleted in a future version of the interface.

None of the access methods provide any form of concurrent access, locking, or transactions.

NAME

des_crypt, ecb_crypt, cbc_crypt, des_setparity, DES_FAILED − fast DES encryption

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <rpc/des_crypt.h>

[[deprecated]] int ecb_crypt(char ****key*, char** *data***[.***datalen***],**
unsigned int *datalen***, unsigned int** *mode***);**
[[deprecated]] int cbc_crypt(char ****key*, char** *data***[.***datalen***],**
unsigned int *datalen***, unsigned int** *mode***,**
char ****ivec*);**

[[deprecated]] void des_setparity(char ****key*);**

[[deprecated]] int DES_FAILED(int *status***);**

DESCRIPTION

ecb_crypt() and **cbc_crypt**() implement the NBS DES (Data Encryption Standard). These routines are faster and more general purpose than *crypt*(3). They also are able to utilize DES hardware if it is available. **ecb_crypt**() encrypts in ECB (Electronic Code Book) mode, which encrypts blocks of data independently. **cbc_crypt**() encrypts in CBC (Cipher Block Chaining) mode, which chains together successive blocks. CBC mode protects against insertions, deletions, and substitutions of blocks. Also, regularities in the clear text will not appear in the cipher text.

Here is how to use these routines. The first argument, *key*, is the 8-byte encryption key with parity. To set the key's parity, which for DES is in the low bit of each byte, use **des_setparity**(). The second argument, *data*, contains the data to be encrypted or decrypted. The third argument, *datalen*, is the length in bytes of *data*, which must be a multiple of 8. The fourth argument, *mode*, is formed by ORing together some things. For the encryption direction OR in either **DES_ENCRYPT** or **DES_DECRYPT**. For software versus hardware encryption, OR in either **DES_HW** or **DES_SW**. If **DES_HW** is specified, and there is no hardware, then the encryption is performed in software and the routine returns **DESERR_NOHWDEVICE**. For **cbc_crypt**(), the argument *ivec* is the 8-byte initialization vector for the chaining. It is updated to the next initialization vector upon return.

RETURN VALUE

DESERR_NONE
No error.

DESERR_NOHWDEVICE
Encryption succeeded, but done in software instead of the requested hardware.

DESERR_HWERROR
An error occurred in the hardware or driver.

DESERR_BADPARAM
Bad argument to routine.

Given a result status *stat*, the macro **DES_FAILED(***stat***)** is false only for the first two statuses.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ecb_crypt(), **cbc_crypt**(), **des_setparity**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

4.3BSD. glibc 2.1. Removed in glibc 2.28.

Because they employ the DES block cipher, which is no longer considered secure, these functions were removed. Applications should switch to a modern cryptography library, such as **libgcrypt**.

NAME

difftime − calculate time difference

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <time.h>

double difftime(time_t *time1***, time_t** *time0***);**

DESCRIPTION

The **difftime**() function returns the number of seconds elapsed between time *time1* and time *time0*, represented as a *double*. Each time is a count of seconds.

difftime(b, a) acts like *(b−a)* except that the result does not overflow and is rounded to *double*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
difftime()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

NAME

dirfd − get directory stream file descriptor

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <dirent.h>

int dirfd(DIR *dirp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

dirfd():

```
/* Since glibc 2.10: */ _POSIX_C_SOURCE >= 200809L
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

DESCRIPTION

The function **dirfd**() returns the file descriptor associated with the directory stream *dirp*.

This file descriptor is the one used internally by the directory stream. As a result, it is useful only for functions which do not depend on or alter the file position, such as *fstat*(2) and *fchdir*(2). It will be automatically closed when *closedir*(3) is called.

RETURN VALUE

On success, **dirfd**() returns a file descriptor (a nonnegative integer). On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

POSIX.1-2008 specifies two errors, neither of which is returned by the current implementation.

EINVAL
: *dirp* does not refer to a valid directory stream.

ENOTSUP
: The implementation does not support the association of a file descriptor with a directory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
dirfd()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

NAME

div, ldiv, lldiv, imaxdiv − compute quotient and remainder of an integer division

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

div_t div(int numerator, int denominator);
ldiv_t ldiv(long numerator, long denominator);
lldiv_t lldiv(long long numerator, long long denominator);

#include <inttypes.h>

imaxdiv_t imaxdiv(intmax_t numerator, intmax_t denominator);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

lldiv():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **div**() function computes the value *numerator*/*denominator* and returns the quotient and remainder in a structure named *div_t* that contains two integer members (in unspecified order) named *quot* and *rem*. The quotient is rounded toward zero. The result satisfies *quot***denominator*+*rem* = *numerator*.

The **ldiv**(), **lldiv**(), and **imaxdiv**() functions do the same, dividing numbers of the indicated type and returning the result in a structure of the indicated name, in all cases with fields *quot* and *rem* of the same type as the function arguments.

RETURN VALUE

The *div_t* (etc.) structure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
div(), **ldiv**(), **lldiv**(), **imaxdiv**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, C99, SVr4, 4.3BSD.

lldiv() and **imaxdiv**() were added in C99.

EXAMPLES

After

```
div_t q = div(−5, 3);
```

the values *q.quot* and *q.rem* are −1 and −2, respectively.

NAME

dl_iterate_phdr − walk through list of shared objects

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <link.h>

int dl_iterate_phdr(
      int (*callback)(struct dl_phdr_info *info,
                      size_t size, void *data),
      void *data);
```

DESCRIPTION

The **dl_iterate_phdr**() function allows an application to inquire at run time to find out which shared objects it has loaded, and the order in which they were loaded.

The **dl_iterate_phdr**() function walks through the list of an application's shared objects and calls the function *callback* once for each object, until either all shared objects have been processed or *callback* returns a nonzero value.

Each call to *callback* receives three arguments: *info*, which is a pointer to a structure containing information about the shared object; *size*, which is the size of the structure pointed to by *info*; and *data*, which is a copy of whatever value was passed by the calling program as the second argument (also named *data*) in the call to **dl_iterate_phdr**().

The *info* argument is a structure of the following type:

```
struct dl_phdr_info {
    ElfW(Addr)        dlpi_addr;  /* Base address of object */
    const char       *dlpi_name;  /* (Null-terminated) name of
                                     object */
    const ElfW(Phdr) *dlpi_phdr;  /* Pointer to array of
                                     ELF program headers
                                     for this object */
    ElfW(Half)        dlpi_phnum; /* # of items in dlpi_phdr */

    /* The following fields were added in glibc 2.4, after the first
       version of this structure was available.  Check the size
       argument passed to the dl_iterate_phdr callback to determine
       whether or not each later member is available.  */

    unsigned long long dlpi_adds;
                    /* Incremented when a new object may
                       have been added */
    unsigned long long dlpi_subs;
                    /* Incremented when an object may
                       have been removed */
    size_t dlpi_tls_modid;
                    /* If there is a PT_TLS segment, its module
                       ID as used in TLS relocations, else zero */
    void  *dlpi_tls_data;
                    /* The address of the calling thread's instance
                       of this module's PT_TLS segment, if it has
                       one and it has been allocated in the calling
                       thread, otherwise a null pointer */
};
```

(The *ElfW*() macro definition turns its argument into the name of an ELF data type suitable for the hardware architecture. For example, on a 32-bit platform, *ElfW(Addr)* yields the data type name *Elf32_Addr*. Further information on these types can be found in the <*elf.h*> and <*link.h*> header files.)

The *dlpi_addr* field indicates the base address of the shared object (i.e., the difference between the

virtual memory address of the shared object and the offset of that object in the file from which it was loaded). The *dlpi_name* field is a null-terminated string giving the pathname from which the shared object was loaded.

To understand the meaning of the *dlpi_phdr* and *dlpi_phnum* fields, we need to be aware that an ELF shared object consists of a number of segments, each of which has a corresponding program header describing the segment. The *dlpi_phdr* field is a pointer to an array of the program headers for this shared object. The *dlpi_phnum* field indicates the size of this array.

These program headers are structures of the following form:

```
typedef struct {
    Elf32_Word  p_type;    /* Segment type */
    Elf32_Off   p_offset;  /* Segment file offset */
    Elf32_Addr  p_vaddr;   /* Segment virtual address */
    Elf32_Addr  p_paddr;   /* Segment physical address */
    Elf32_Word  p_filesz;  /* Segment size in file */
    Elf32_Word  p_memsz;   /* Segment size in memory */
    Elf32_Word  p_flags;   /* Segment flags */
    Elf32_Word  p_align;   /* Segment alignment */
} Elf32_Phdr;
```

Note that we can calculate the location of a particular program header, *x*, in virtual memory using the formula:

```
addr == info->dlpi_addr + info->dlpi_phdr[x].p_vaddr;
```

Possible values for *p_type* include the following (see <*elf.h*> for further details):

```
#define PT_LOAD         1    /* Loadable program segment */
#define PT_DYNAMIC      2    /* Dynamic linking information */
#define PT_INTERP       3    /* Program interpreter */
#define PT_NOTE         4    /* Auxiliary information */
#define PT_SHLIB        5    /* Reserved */
#define PT_PHDR         6    /* Entry for header table itself */
#define PT_TLS          7    /* Thread-local storage segment */
#define PT_GNU_EH_FRAME 0x6474e550 /* GCC .eh_frame_hdr segment */
#define PT_GNU_STACK  0x6474e551 /* Indicates stack executability */
#define PT_GNU_RELRO  0x6474e552 /* Read-only after relocation */
```

RETURN VALUE

The **dl_iterate_phdr**() function returns whatever value was returned by the last call to *callback*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
dl_iterate_phdr()	Thread safety	MT-Safe

VERSIONS

Various other systems provide a version of this function, although details of the returned *dl_phdr_info* structure differ. On the BSDs and Solaris, the structure includes the fields *dlpi_addr*, *dlpi_name*, *dlpi_phdr*, and *dlpi_phnum* in addition to other implementation-specific fields.

Future versions of the C library may add further fields to the *dl_phdr_info* structure; in that event, the *size* argument provides a mechanism for the callback function to discover whether it is running on a system with added fields.

STANDARDS

None.

HISTORY

glibc 2.2.4.

NOTES

The first object visited by *callback* is the main program. For the main program, the *dlpi_name* field will be an empty string.

EXAMPLES

The following program displays a list of pathnames of the shared objects it has loaded. For each shared object, the program lists some information (virtual address, size, flags, and type) for each of the objects ELF segments.

The following shell session demonstrates the output produced by the program on an x86-64 system. The first shared object for which output is displayed (where the name is an empty string) is the main program.

```
$ ./a.out

Executable and Linking Format Specification, available at various locations online.

NAME

dladdr, dladdr1 − translate address to symbolic information

LIBRARY

Dynamic linking library (*libdl*, *−ldl*)

SYNOPSIS

```
#define _GNU_SOURCE
#include <dlfcn.h>

int dladdr(const void *addr, Dl_info *info);
int dladdr1(const void *addr, Dl_info *info, void **extra_info,
      int flags);
```

DESCRIPTION

The function **dladdr**() determines whether the address specified in *addr* is located in one of the shared objects loaded by the calling application. If it is, then **dladdr**() returns information about the shared object and symbol that overlaps *addr*. This information is returned in a *Dl_info* structure:

```
typedef struct {
    const char *dli_fname;  /* Pathname of shared object that
                               contains address */
    void       *dli_fbase;  /* Base address at which shared
                               object is loaded */
    const char *dli_sname;  /* Name of symbol whose definition
                               overlaps addr */
    void       *dli_saddr;  /* Exact address of symbol named
                               in dli_sname */
} Dl_info;
```

If no symbol matching *addr* could be found, then *dli_sname* and *dli_saddr* are set to NULL.

The function **dladdr1**() is like **dladdr**(), but returns additional information via the argument *extra_info*. The information returned depends on the value specified in *flags*, which can have one of the following values:

RTLD_DL_LINKMAP

Obtain a pointer to the link map for the matched file. The *extra_info* argument points to a pointer to a *link_map* structure (i.e., *struct link_map* **), defined in <*link.h*> as:

```
struct link_map {
    ElfW(Addr) l_addr;  /* Difference between the
                           address in the ELF file and
                           the address in memory */
    char      *l_name;  /* Absolute pathname where
                           object was found */
    ElfW(Dyn) *l_ld;    /* Dynamic section of the
                           shared object */
    struct link_map *l_next, *l_prev;
                        /* Chain of loaded objects */

    /* Plus additional fields private to the
       implementation */
};
```

RTLD_DL_SYMENT

Obtain a pointer to the ELF symbol table entry of the matching symbol. The *extra_info* argument is a pointer to a symbol pointer: *const ElfW(Sym)* **. The *ElfW*() macro definition turns its argument into the name of an ELF data type suitable for the hardware architecture. For example, on a 64-bit platform, *ElfW(Sym)* yields the data type name *Elf64_Sym*, which is defined in <*elf.h*> as:

```
typedef struct  {
    Elf64_Word    st_name;     /* Symbol name */
    unsigned char st_info;     /* Symbol type and binding */
```

```
    unsigned char st_other;    /* Symbol visibility */
    Elf64_Section st_shndx;    /* Section index */
    Elf64_Addr    st_value;    /* Symbol value */
    Elf64_Xword   st_size;     /* Symbol size */
} Elf64_Sym;
```

The *st_name* field is an index into the string table.

The *st_info* field encodes the symbol's type and binding. The type can be extracted using the macro **ELF64_ST_TYPE(st_info)** (or **ELF32_ST_TYPE()** on 32-bit platforms), which yields one of the following values:

Value	Description
STT_NOTYPE	Symbol type is unspecified
STT_OBJECT	Symbol is a data object
STT_FUNC	Symbol is a code object
STT_SECTION	Symbol associated with a section
STT_FILE	Symbol's name is filename
STT_COMMON	Symbol is a common data object
STT_TLS	Symbol is thread-local data object
STT_GNU_IFUNC	Symbol is indirect code object

The symbol binding can be extracted from the *st_info* field using the macro **ELF64_ST_BIND(st_info)** (or **ELF32_ST_BIND()** on 32-bit platforms), which yields one of the following values:

Value	Description
STB_LOCAL	Local symbol
STB_GLOBAL	Global symbol
STB_WEAK	Weak symbol
STB_GNU_UNIQUE	Unique symbol

The *st_other* field contains the symbol's visibility, which can be extracted using the macro **ELF64_ST_VISIBILITY(st_info)** (or **ELF32_ST_VISIBILITY()** on 32-bit platforms), which yields one of the following values:

Value	Description
STV_DEFAULT	Default symbol visibility rules
STV_INTERNAL	Processor-specific hidden class
STV_HIDDEN	Symbol unavailable in other modules
STV_PROTECTED	Not preemptible, not exported

RETURN VALUE

On success, these functions return a nonzero value. If the address specified in *addr* could be matched to a shared object, but not to a symbol in the shared object, then the *info->dli_sname* and *info->dli_saddr* fields are set to NULL.

If the address specified in *addr* could not be matched to a shared object, then these functions return 0. In this case, an error message is *not* available via *dlerror*(3).

ATTRIBUTES

HISTORY

dladdr()
: glibc 2.0.

dladdr1()
: glibc 2.3.3.

Solaris.

BUGS

Sometimes, the function pointers you pass to **dladdr**() may surprise you. On some architectures (notably i386 and x86-64), *dli_fname* and *dli_fbase* may end up pointing back at the object from which you called **dladdr**(), even if the function used as an argument should come from a dynamically linked library.

The problem is that the function pointer will still be resolved at compile time, but merely point to the *plt* (Procedure Linkage Table) section of the original object (which dispatches the call after asking the dynamic linker to resolve the symbol). To work around this, you can try to compile the code to be position-independent: then, the compiler cannot prepare the pointer at compile time any more and *gcc*(1) will generate code that just loads the final symbol address from the *got* (Global Offset Table) at run time before passing it to **dladdr**().

NAME

dlerror − obtain error diagnostic for functions in the dlopen API

LIBRARY

Dynamic linking library (*libdl*, *−ldl*)

SYNOPSIS

#include <dlfcn.h>

char *dlerror(void);

DESCRIPTION

The **dlerror**() function returns a human-readable, null-terminated string describing the most recent error that occurred from a call to one of the functions in the dlopen API since the last call to **dlerror**(). The returned string does *not* include a trailing newline.

dlerror() returns NULL if no errors have occurred since initialization or since it was last called.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
dlerror()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.0. POSIX.1-2001.

SunOS.

NOTES

The message returned by **dlerror**() may reside in a statically allocated buffer that is overwritten by subsequent **dlerror**() calls.

EXAMPLES

See *dlopen*(3).

NAME

dlinfo − obtain information about a dynamically loaded object

LIBRARY

Dynamic linking library (*libdl*, *−ldl*)

SYNOPSIS

#define _GNU_SOURCE
#include <link.h>
#include <dlfcn.h>

int dlinfo(void *restrict handle**, int** request**, void *restrict** info**);**

DESCRIPTION

The **dlinfo**() function obtains information about the dynamically loaded object referred to by *handle* (typically obtained by an earlier call to *dlopen*(3) or *dlmopen*(3)). The *request* argument specifies which information is to be returned. The *info* argument is a pointer to a buffer used to store information returned by the call; the type of this argument depends on *request*.

The following values are supported for *request* (with the corresponding type for *info* shown in parentheses):

RTLD_DI_LMID (*Lmid_t* *)
Obtain the ID of the link-map list (namespace) in which *handle* is loaded.

RTLD_DI_LINKMAP (*struct link_map* **)
Obtain a pointer to the *link_map* structure corresponding to *handle*. The *info* argument points to a pointer to a *link_map* structure, defined in <*link.h*> as:

```
struct link_map {
    ElfW(Addr) l_addr;  /* Difference between the
                           address in the ELF file and
                           the address in memory */
    char      *l_name;  /* Absolute pathname where
                           object was found */
    ElfW(Dyn) *l_ld;    /* Dynamic section of the
                           shared object */
    struct link_map *l_next, *l_prev;
                        /* Chain of loaded objects */

    /* Plus additional fields private to the
       implementation */
};
```

RTLD_DI_ORIGIN (*char* *)
Copy the pathname of the origin of the shared object corresponding to *handle* to the location pointed to by *info*.

RTLD_DI_SERINFO (*Dl_serinfo* *)
Obtain the library search paths for the shared object referred to by *handle*. The *info* argument is a pointer to a *Dl_serinfo* that contains the search paths. Because the number of search paths may vary, the size of the structure pointed to by *info* can vary. The **RTLD_DI_SERINFOSIZE** request described below allows applications to size the buffer suitably. The caller must perform the following steps:

(1) Use a **RTLD_DI_SERINFOSIZE** request to populate a *Dl_serinfo* structure with the size (*dls_size*) of the structure needed for the subsequent **RTLD_DI_SERINFO** request.

(2) Allocate a *Dl_serinfo* buffer of the correct size (*dls_size*).

(3) Use a further **RTLD_DI_SERINFOSIZE** request to populate the *dls_size* and *dls_cnt* fields of the buffer allocated in the previous step.

(4) Use a **RTLD_DI_SERINFO** to obtain the library search paths.

The *Dl_serinfo* structure is defined as follows:

```
typedef struct {
    size_t dls_size;           /* Size in bytes of
                                  the whole buffer */
    unsigned int dls_cnt;      /* Number of elements
                                  in 'dls_serpath' */
    Dl_serpath dls_serpath[1]; /* Actually longer,
                                  'dls_cnt' elements */
} Dl_serinfo;
```

Each of the *dls_serpath* elements in the above structure is a structure of the following form:

```
typedef struct {
    char *dls_name;            /* Name of library search
                                  path directory */
    unsigned int dls_flags;    /* Indicates where this
                                  directory came from */
} Dl_serpath;
```

The *dls_flags* field is currently unused, and always contains zero.

RTLD_DI_SERINFOSIZE (*Dl_serinfo **)
Populate the *dls_size* and *dls_cnt* fields of the *Dl_serinfo* structure pointed to by *info* with values suitable for allocating a buffer for use in a subsequent **RTLD_DI_SERINFO** request.

RTLD_DI_TLS_MODID (*size_t **, since glibc 2.4)
Obtain the module ID of this shared object's TLS (thread-local storage) segment, as used in TLS relocations. If this object does not define a TLS segment, zero is placed in **info*.

RTLD_DI_TLS_DATA (*void ***, since glibc 2.4)
Obtain a pointer to the calling thread's TLS block corresponding to this shared object's TLS segment. If this object does not define a PT_TLS segment, or if the calling thread has not allocated a block for it, NULL is placed in **info*.

RETURN VALUE

On success, **dlinfo**() returns 0. On failure, it returns −1; the cause of the error can be diagnosed using *dlerror*(3).

ATTRIBUTES

STANDARDS

GNU.

HISTORY

glibc 2.3.3. Solaris.

EXAMPLES

The program below opens a shared objects using *dlopen*(3) and then uses the **RTLD_DI_SERINFOSIZE** and **RTLD_DI_SERINFO** requests to obtain the library search path list for the library. Here is an example of what we might see when running the program:

```
$ ./a.out /lib64/libm.so.6
dls_serpath[0].dls_name = /lib64
dls_serpath[1].dls_name = /usr/lib64
```

Program source

```
#define _GNU_SOURCE
#include <dlfcn.h>
#include <link.h>
#include <stdio.h>
#include <stdlib.h>
```

```
int
main(int argc, char *argv[])
{
    void *handle;
    Dl_serinfo serinfo;
    Dl_serinfo *sip;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s <libpath>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    /* Obtain a handle for shared object specified on command line. */

    handle = dlopen(argv[1], RTLD_NOW);
    if (handle == NULL) {
        fprintf(stderr, "dlopen() failed: %s\n", dlerror());
        exit(EXIT_FAILURE);
    }

    /* Discover the size of the buffer that we must pass to
       RTLD_DI_SERINFO. */

    if (dlinfo(handle, RTLD_DI_SERINFOSIZE, &serinfo) == -1) {
        fprintf(stderr, "RTLD_DI_SERINFOSIZE failed: %s\n", dlerror());
        exit(EXIT_FAILURE);
    }

    /* Allocate the buffer for use with RTLD_DI_SERINFO. */

    sip = malloc(serinfo.dls_size);
    if (sip == NULL) {
        perror("malloc");
        exit(EXIT_FAILURE);
    }

    /* Initialize the 'dls_size' and 'dls_cnt' fields in the newly
       allocated buffer. */

    if (dlinfo(handle, RTLD_DI_SERINFOSIZE, sip) == -1) {
        fprintf(stderr, "RTLD_DI_SERINFOSIZE failed: %s\n", dlerror());
        exit(EXIT_FAILURE);
    }

    /* Fetch and print library search list. */

    if (dlinfo(handle, RTLD_DI_SERINFO, sip) == -1) {
        fprintf(stderr, "RTLD_DI_SERINFO failed: %s\n", dlerror());
        exit(EXIT_FAILURE);
    }

    for (size_t j = 0; j < serinfo.dls_cnt; j++)
        printf("dls_serpath[%zu].dls_name = %s\n",
               j, sip->dls_serpath[j].dls_name);

    exit(EXIT_SUCCESS);
}
```

NAME

dlclose, dlopen, dlmopen − open and close a shared object

LIBRARY

Dynamic linking library (*libdl*, *−ldl*)

SYNOPSIS

```
#include <dlfcn.h>

void *dlopen(const char *filename, int flags);
int dlclose(void *handle);

#define _GNU_SOURCE
#include <dlfcn.h>

void *dlmopen(Lmid_t lmid, const char *filename, int flags);
```

DESCRIPTION

dlopen()

The function **dlopen**() loads the dynamic shared object (shared library) file named by the null-terminated string *filename* and returns an opaque "handle" for the loaded object. This handle is employed with other functions in the dlopen API, such as *dlsym*(3), *dladdr*(3), *dlinfo*(3), and **dlclose**().

If *filename* is NULL, then the returned handle is for the main program. If *filename* contains a slash ("/"), then it is interpreted as a (relative or absolute) pathname. Otherwise, the dynamic linker searches for the object as follows (see *ld.so*(8) for further details):

- (ELF only) If the calling object (i.e., the shared library or executable from which **dlopen**() is called) contains a DT_RPATH tag, and does not contain a DT_RUNPATH tag, then the directories listed in the DT_RPATH tag are searched.
- If, at the time that the program was started, the environment variable **LD_LIBRARY_PATH** was defined to contain a colon-separated list of directories, then these are searched. (As a security measure, this variable is ignored for set-user-ID and set-group-ID programs.)
- (ELF only) If the calling object contains a DT_RUNPATH tag, then the directories listed in that tag are searched.
- The cache file */etc/ld.so.cache* (maintained by *ldconfig*(8)) is checked to see whether it contains an entry for *filename*.
- The directories */lib* and */usr/lib* are searched (in that order).

If the object specified by *filename* has dependencies on other shared objects, then these are also automatically loaded by the dynamic linker using the same rules. (This process may occur recursively, if those objects in turn have dependencies, and so on.)

One of the following two values must be included in *flags*:

RTLD_LAZY
: Perform lazy binding. Resolve symbols only as the code that references them is executed. If the symbol is never referenced, then it is never resolved. (Lazy binding is performed only for function references; references to variables are always immediately bound when the shared object is loaded.) Since glibc 2.1.1, this flag is overridden by the effect of the **LD_BIND_NOW** environment variable.

RTLD_NOW
: If this value is specified, or the environment variable **LD_BIND_NOW** is set to a nonempty string, all undefined symbols in the shared object are resolved before **dlopen**() returns. If this cannot be done, an error is returned.

Zero or more of the following values may also be ORed in *flags*:

RTLD_GLOBAL
: The symbols defined by this shared object will be made available for symbol resolution of subsequently loaded shared objects.

RTLD_LOCAL
: This is the converse of **RTLD_GLOBAL**, and the default if neither flag is specified. Symbols defined in this shared object are not made available to resolve references in subsequently

loaded shared objects.

RTLD_NODELETE (since glibc 2.2)
Do not unload the shared object during **dlclose**(). Consequently, the object's static and global variables are not reinitialized if the object is reloaded with **dlopen**() at a later time.

RTLD_NOLOAD (since glibc 2.2)
Don't load the shared object. This can be used to test if the object is already resident (**dlopen**() returns NULL if it is not, or the object's handle if it is resident). This flag can also be used to promote the flags on a shared object that is already loaded. For example, a shared object that was previously loaded with **RTLD_LOCAL** can be reopened with **RTLD_NOLOAD | RTLD_GLOBAL**.

RTLD_DEEPBIND (since glibc 2.3.4)
Place the lookup scope of the symbols in this shared object ahead of the global scope. This means that a self-contained object will use its own symbols in preference to global symbols with the same name contained in objects that have already been loaded.

If *filename* is NULL, then the returned handle is for the main program. When given to *dlsym*(3), this handle causes a search for a symbol in the main program, followed by all shared objects loaded at program startup, and then all shared objects loaded by **dlopen**() with the flag **RTLD_GLOBAL**.

Symbol references in the shared object are resolved using (in order): symbols in the link map of objects loaded for the main program and its dependencies; symbols in shared objects (and their dependencies) that were previously opened with **dlopen**() using the **RTLD_GLOBAL** flag; and definitions in the shared object itself (and any dependencies that were loaded for that object).

Any global symbols in the executable that were placed into its dynamic symbol table by *ld*(1) can also be used to resolve references in a dynamically loaded shared object. Symbols may be placed in the dynamic symbol table either because the executable was linked with the flag "−rdynamic" (or, synonymously, "−−export−dynamic"), which causes all of the executable's global symbols to be placed in the dynamic symbol table, or because *ld*(1) noted a dependency on a symbol in another object during static linking.

If the same shared object is opened again with **dlopen**(), the same object handle is returned. The dynamic linker maintains reference counts for object handles, so a dynamically loaded shared object is not deallocated until **dlclose**() has been called on it as many times as **dlopen**() has succeeded on it. Constructors (see below) are called only when the object is actually loaded into memory (i.e., when the reference count increases to 1).

A subsequent **dlopen**() call that loads the same shared object with **RTLD_NOW** may force symbol resolution for a shared object earlier loaded with **RTLD_LAZY**. Similarly, an object that was previously opened with **RTLD_LOCAL** can be promoted to **RTLD_GLOBAL** in a subsequent **dlopen**().

If **dlopen**() fails for any reason, it returns NULL.

dlmopen()
This function performs the same task as **dlopen**()—the *filename* and *flags* arguments, as well as the return value, are the same, except for the differences noted below.

The **dlmopen**() function differs from **dlopen**() primarily in that it accepts an additional argument, *lmid*, that specifies the link-map list (also referred to as a *namespace*) in which the shared object should be loaded. (By comparison, **dlopen**() adds the dynamically loaded shared object to the same namespace as the shared object from which the **dlopen**() call is made.) The *Lmid_t* type is an opaque handle that refers to a namespace.

The *lmid* argument is either the ID of an existing namespace (which can be obtained using the *dlinfo*(3) **RTLD_DI_LMID** request) or one of the following special values:

LM_ID_BASE
Load the shared object in the initial namespace (i.e., the application's namespace).

LM_ID_NEWLM
Create a new namespace and load the shared object in that namespace. The object must have been correctly linked to reference all of the other shared objects that it requires, since the new namespace is initially empty.

If *filename* is NULL, then the only permitted value for *lmid* is **LM_ID_BASE**.

dlclose()

The function **dlclose**() decrements the reference count on the dynamically loaded shared object referred to by *handle*.

If the object's reference count drops to zero and no symbols in this object are required by other objects, then the object is unloaded after first calling any destructors defined for the object. (Symbols in this object might be required in another object because this object was opened with the **RTLD_GLOBAL** flag and one of its symbols satisfied a relocation in another object.)

All shared objects that were automatically loaded when **dlopen**() was invoked on the object referred to by *handle* are recursively closed in the same manner.

A successful return from **dlclose**() does not guarantee that the symbols associated with *handle* are removed from the caller's address space. In addition to references resulting from explicit **dlopen**() calls, a shared object may have been implicitly loaded (and reference counted) because of dependencies in other shared objects. Only when all references have been released can the shared object be removed from the address space.

RETURN VALUE

On success, **dlopen**() and **dlmopen**() return a non-NULL handle for the loaded object. On error (file could not be found, was not readable, had the wrong format, or caused errors during loading), these functions return NULL.

On success, **dlclose**() returns 0; on error, it returns a nonzero value.

Errors from these functions can be diagnosed using *dlerror*(3).

NOTES

dlmopen() and namespaces

A link-map list defines an isolated namespace for the resolution of symbols by the dynamic linker. Within a namespace, dependent shared objects are implicitly loaded according to the usual rules, and symbol references are likewise resolved according to the usual rules, but such resolution is confined to the definitions provided by the objects that have been (explicitly and implicitly) loaded into the namespace.

The **dlmopen**() function permits object-load isolation—the ability to load a shared object in a new namespace without exposing the rest of the application to the symbols made available by the new object. Note that the use of the **RTLD_LOCAL** flag is not sufficient for this purpose, since it prevents a shared object's symbols from being available to *any* other shared object. In some cases, we may want to make the symbols provided by a dynamically loaded shared object available to (a subset of) other shared objects without exposing those symbols to the entire application. This can be achieved by using

a separate namespace and the **RTLD_GLOBAL** flag.

The **dlmopen**() function also can be used to provide better isolation than the **RTLD_LOCAL** flag. In particular, shared objects loaded with **RTLD_LOCAL** may be promoted to **RTLD_GLOBAL** if they are dependencies of another shared object loaded with **RTLD_GLOBAL**. Thus, **RTLD_LOCAL** is insufficient to isolate a loaded shared object except in the (uncommon) case where one has explicit control over all shared object dependencies.

Possible uses of **dlmopen**() are plugins where the author of the plugin-loading framework can't trust the plugin authors and does not wish any undefined symbols from the plugin framework to be resolved to plugin symbols. Another use is to load the same object more than once. Without the use of **dlmopen**(), this would require the creation of distinct copies of the shared object file. Using **dlmopen**(), this can be achieved by loading the same shared object file into different namespaces.

The glibc implementation supports a maximum of 16 namespaces.

Initialization and finalization functions

Shared objects may export functions using the **__attribute__((constructor))** and **__attribute__((destructor))** function attributes. Constructor functions are executed before **dlopen**() returns, and destructor functions are executed before **dlclose**() returns. A shared object may export multiple constructors and destructors, and priorities can be associated with each function to determine the order in which they are executed. See the **gcc** info pages (under "Function attributes") for further information.

An older method of (partially) achieving the same result is via the use of two special symbols recognized by the linker: **_init** and **_fini**. If a dynamically loaded shared object exports a routine named **_init**(), then that code is executed after loading a shared object, before **dlopen**() returns. If the shared object exports a routine named **_fini**(), then that routine is called just before the object is unloaded. In this case, one must avoid linking against the system startup files, which contain default versions of these files; this can be done by using the *gcc*(1) *−nostartfiles* command-line option.

Use of **_init** and **_fini** is now deprecated in favor of the aforementioned constructors and destructors, which among other advantages, permit multiple initialization and finalization functions to be defined.

Since glibc 2.2.3, *atexit*(3) can be used to register an exit handler that is automatically called when a shared object is unloaded.

History

These functions are part of the dlopen API, derived from SunOS.

BUGS

As at glibc 2.24, specifying the **RTLD_GLOBAL** flag when calling **dlmopen**() generates an error. Furthermore, specifying **RTLD_GLOBAL** when calling **dlopen**() results in a program crash (**SIGSEGV**) if the call is made from any object loaded in a namespace other than the initial namespace.

EXAMPLES

The program below loads the (glibc) math library, looks up the address of the *cos*(3) function, and prints the cosine of 2.0. The following is an example of building and running the program:

```
$ cc dlopen_demo.c -ldl
$ ./a.out
-0.416147
```

Program source

```
#include <dlfcn.h>
#include <stdio.h>
#include <stdlib.h>

#include <gnu/lib-names.h>  /* Defines LIBM_SO (which will be a
                               string such as "libm.so.6") */
int
main(void)
{
    void *handle;
    double (*cosine)(double);
```

```
        char *error;

        handle = dlopen(LIBM_SO, RTLD_LAZY);
        if (!handle) {
            fprintf(stderr, "%s\n", dlerror());
            exit(EXIT_FAILURE);
        }

        dlerror();    /* Clear any existing error */

        cosine = (double (*)(double)) dlsym(handle, "cos");

        /* According to the ISO C standard, casting between function
           pointers and 'void *', as done above, produces undefined results.
           POSIX.1-2001 and POSIX.1-2008 accepted this state of affairs and
           proposed the following workaround:

               *(void **) (&cosine) = dlsym(handle, "cos");

           This (clumsy) cast conforms with the ISO C standard and will
           avoid any compiler warnings.

           The 2013 Technical Corrigendum 1 to POSIX.1-2008 improved matters
           by requiring that conforming implementations support casting
           'void *' to a function pointer.  Nevertheless, some compilers
           (e.g., gcc with the '-pedantic' option) may complain about the
           cast used in this program. */

        error = dlerror();
        if (error != NULL) {
            fprintf(stderr, "%s\n", error);
            exit(EXIT_FAILURE);
        }

        printf("%f\n", (*cosine)(2.0));
        dlclose(handle);
        exit(EXIT_SUCCESS);
    }
```

NAME

dlsym, dlvsym − obtain address of a symbol in a shared object or executable

LIBRARY

Dynamic linking library (*libdl*, *−ldl*)

SYNOPSIS

```
#include <dlfcn.h>

void *dlsym(void *restrict handle, const char *restrict symbol);

#define _GNU_SOURCE
#include <dlfcn.h>

void *dlvsym(void *restrict handle, const char *restrict symbol,
        const char *restrict version);
```

DESCRIPTION

The function **dlsym**() takes a "handle" of a dynamic loaded shared object returned by *dlopen*(3) along with a null-terminated symbol name, and returns the address where that symbol is loaded into memory. If the symbol is not found, in the specified object or any of the shared objects that were automatically loaded by *dlopen*(3) when that object was loaded, **dlsym**() returns NULL. (The search performed by **dlsym**() is breadth first through the dependency tree of these shared objects.)

In unusual cases (see NOTES) the value of the symbol could actually be NULL. Therefore, a NULL return from **dlsym**() need not indicate an error. The correct way to distinguish an error from a symbol whose value is NULL is to call *dlerror*(3) to clear any old error conditions, then call **dlsym**(), and then call *dlerror*(3) again, saving its return value into a variable, and check whether this saved value is not NULL.

There are two special pseudo-handles that may be specified in *handle*:

RTLD_DEFAULT
: Find the first occurrence of the desired symbol using the default shared object search order. The search will include global symbols in the executable and its dependencies, as well as symbols in shared objects that were dynamically loaded with the **RTLD_GLOBAL** flag.

RTLD_NEXT
: Find the next occurrence of the desired symbol in the search order after the current object. This allows one to provide a wrapper around a function in another shared object, so that, for example, the definition of a function in a preloaded shared object (see **LD_PRELOAD** in *ld.so*(8)) can find and invoke the "real" function provided in another shared object (or for that matter, the "next" definition of the function in cases where there are multiple layers of preloading).

The **_GNU_SOURCE** feature test macro must be defined in order to obtain the definitions of **RTLD_DEFAULT** and **RTLD_NEXT** from <*dlfcn.h*>.

The function **dlvsym**() does the same as **dlsym**() but takes a version string as an additional argument.

RETURN VALUE

On success, these functions return the address associated with *symbol*. On failure, they return NULL; the cause of the error can be diagnosed using *dlerror*(3).

ATTRIBUTES

dlvsym()
glibc 2.1.

NOTES

There are several scenarios when the address of a global symbol is NULL. For example, a symbol can be placed at zero address by the linker, via a linker script or with −−*defsym* command-line option. Undefined weak symbols also have NULL value. Finally, the symbol value may be the result of a GNU indirect function (IFUNC) resolver function that returns NULL as the resolved value. In the latter case, **dlsym**() also returns NULL without error. However, in the former two cases, the behavior of GNU dynamic linker is inconsistent: relocation processing succeeds and the symbol can be observed to have NULL value, but **dlsym**() fails and **dlerror**() indicates a lookup error.

History

The **dlsym**() function is part of the dlopen API, derived from SunOS. That system does not have **dlvsym**().

EXAMPLES

See *dlopen*(3).

NAME

drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 − generate uniformly distributed pseudo-random numbers

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

double drand48(void);
double erand48(unsigned short xsubi[3]);

long lrand48(void);
long nrand48(unsigned short xsubi[3]);

long mrand48(void);
long jrand48(unsigned short xsubi[3]);

void srand48(long seedval);
unsigned short *seed48(unsigned short seed16v[3]);
void lcong48(unsigned short param[7]);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:
_XOPEN_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE

DESCRIPTION

These functions generate pseudo-random numbers using the linear congruential algorithm and 48-bit integer arithmetic.

The **drand48**() and **erand48**() functions return nonnegative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).

The **lrand48**() and **nrand48**() functions return nonnegative long integers uniformly distributed over the interval [0, 2^31).

The **mrand48**() and **jrand48**() functions return signed long integers uniformly distributed over the interval [−2^31, 2^31).

The **srand48**(), **seed48**(), and **lcong48**() functions are initialization functions, one of which should be called before using **drand48**(), **lrand48**(), or **mrand48**(). The functions **erand48**(), **nrand48**(), and **jrand48**() do not require an initialization function to be called first.

All the functions work by generating a sequence of 48-bit integers, *Xi*, according to the linear congruential formula:

```
Xn+1 = (aXn + c) mod m, where n >= 0
```

The parameter *m* = 2^48, hence 48-bit integer arithmetic is performed. Unless **lcong48**() is called, *a* and *c* are given by:

```
a = 0x5DEECE66D
c = 0xB
```

The value returned by any of the functions **drand48**(), **erand48**(), **lrand48**(), **nrand48**(), **mrand48**(), or **jrand48**() is computed by first generating the next 48-bit *Xi* in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, is copied from the high-order bits of *Xi* and transformed into the returned value.

The functions **drand48**(), **lrand48**(), and **mrand48**() store the last 48-bit *Xi* generated in an internal buffer. The functions **erand48**(), **nrand48**(), and **jrand48**() require the calling program to provide storage for the successive *Xi* values in the array argument *xsubi*. The functions are initialized by placing the initial value of *Xi* into the array before calling the function for the first time.

The initializer function **srand48**() sets the high order 32-bits of *Xi* to the argument *seedval*. The low order 16-bits are set to the arbitrary value 0x330E.

The initializer function **seed48**() sets the value of *Xi* to the 48-bit value specified in the array argument *seed16v*. The previous value of *Xi* is copied into an internal buffer and a pointer to this buffer is returned by **seed48**().

The initialization function **lcong48**() allows the user to specify initial values for *Xi*, *a*, and *c*. Array argument elements *param[0−2]* specify *Xi*, *param[3−5]* specify *a*, and *param[6]* specifies *c*. After **lcong48**() has been called, a subsequent call to either **srand48**() or **seed48**() will restore the standard values of *a* and *c*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
drand48(), **erand48**(), **lrand48**(), **nrand48**(), **mrand48**(), **jrand48**(), **srand48**(), **seed48**(), **lcong48**()	Thread safety	MT-Unsafe race:drand48

The above functions record global state information for the random number generator, so they are not thread-safe.

STANDARDS

POSIX.1-2008.

int seed48_r(unsigned short seed16v[3], struct drand48_data *buffer);
int lcong48_r(unsigned short param[7], struct drand48_data *buffer);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:

```
/* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE
```

DESCRIPTION

These functions are the reentrant analogs of the functions described in *drand48*(3). Instead of modifying the global random generator state, they use the supplied data *buffer*.

Before the first use, this struct must be initialized, for example, by filling it with zeros, or by calling one of the functions **srand48_r**(), **seed48_r**(), or **lcong48_r**().

RETURN VALUE

The return value is 0.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

duplocale − duplicate a locale object

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <locale.h>

locale_t duplocale(locale_t *locobj***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

duplocale():
Since glibc 2.10:
_XOPEN_SOURCE >= 700
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **duplocale**() function creates a duplicate of the locale object referred to by *locobj*.

If *locobj* is **LC_GLOBAL_LOCALE**, **duplocale**() creates a locale object containing a copy of the global locale determined by *setlocale*(3).

RETURN VALUE

On success, **duplocale**() returns a handle for the new locale object. On error, it returns *(locale_t) 0*, and sets *errno* to indicate the error.

ERRORS

ENOMEM
Insufficient memory to create the duplicate locale object.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.3.

NOTES

Duplicating a locale can serve the following purposes:

- To create a copy of a locale object in which one of more categories are to be modified (using *newlocale*(3)).
- To obtain a handle for the current locale which can used in other functions that employ a locale handle, such as *toupper_l*(3). This is done by applying **duplocale**() to the value returned by the following call:

  ```
  loc = uselocale((locale_t) 0);
  ```

  This technique is necessary, because the above *uselocale*(3) call may return the value **LC_GLOBAL_LOCALE**, which results in undefined behavior if passed to functions such as *toupper_l*(3). Calling **duplocale**() can be used to ensure that the **LC_GLOBAL_LOCALE** value is converted into a usable locale object. See EXAMPLES, below.

Each locale object created by **duplocale**() should be deallocated using *freelocale*(3).

EXAMPLES

The program below uses *uselocale*(3) and **duplocale**() to obtain a handle for the current locale which is then passed to *toupper_l*(3). The program takes one command-line argument, a string of characters that is converted to uppercase and displayed on standard output. An example of its use is the following:

```
$ ./a.out abc
ABC
```

Program source

```
#define _XOPEN_SOURCE 700
#include <ctype.h>
```

```
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

#define errExit(msg)    do { perror(msg); exit(EXIT_FAILURE); \
                        } while (0)

int
main(int argc, char *argv[])
{
    locale_t loc, nloc;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s string\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    /* This sequence is necessary, because uselocale() might return
       the value LC_GLOBAL_LOCALE, which can't be passed as an
       argument to toupper_l(). */

    loc = uselocale((locale_t) 0);
    if (loc == (locale_t) 0)
        errExit("uselocale");

    nloc = duplocale(loc);
    if (nloc == (locale_t) 0)
        errExit("duplocale");

    for (char *p = argv[1]; *p; p++)
        putchar(toupper_l(*p, nloc));

    printf("\n");

    freelocale(nloc);

    exit(EXIT_SUCCESS);
}
```

NAME

dysize − get number of days for a given year

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <time.h>

int dysize(int *year***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

dysize():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The function returns 365 for a normal year and 366 for a leap year. The calculation for leap year is based on:

```
(year) %4 == 0 && ((year) %100 != 0 || (year) %400 == 0)
```

The formula is defined in the macro *__isleap(year)* also found in <*time.h*>.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
dysize()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

SunOS 4.x.

This is a compatibility function only. Don’t use it in new programs.

SEE ALSO

strftime(3)

NAME

ecvt, fcvt − convert a floating-point number to a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

[[deprecated]] char *ecvt(double number, int ndigits,
                          int *restrict decpt, int *restrict sign);
[[deprecated]] char *fcvt(double number, int ndigits,
                          int *restrict decpt, int *restrict sign);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ecvt(), **fcvt**():
- Since glibc 2.17
  - (_XOPEN_SOURCE >= 500 && ! (_POSIX_C_SOURCE >= 200809L))
    - || /* glibc >= 2.20 */ _DEFAULT_SOURCE
    - || /* glibc <= 2.19 */ _SVID_SOURCE
- glibc 2.12 to glibc 2.16:
  - (_XOPEN_SOURCE >= 500 && ! (_POSIX_C_SOURCE >= 200112L))
    - || _SVID_SOURCE
- Before glibc 2.12:
  - _SVID_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

The **ecvt**() function converts *number* to a null-terminated string of *ndigits* digits (where *ndigits* is reduced to a system-specific limit determined by the precision of a *double*), and returns a pointer to the string. The high-order digit is nonzero, unless *number* is zero. The low order digit is rounded. The string itself does not contain a decimal point; however, the position of the decimal point relative to the start of the string is stored in **decpt*. A negative value for **decpt* means that the decimal point is to the left of the start of the string. If the sign of *number* is negative, **sign* is set to a nonzero value, otherwise it is set to 0. If *number* is zero, it is unspecified whether **decpt* is 0 or 1.

The **fcvt**() function is identical to **ecvt**(), except that *ndigits* specifies the number of digits after the decimal point.

RETURN VALUE

Both the **ecvt**() and **fcvt**() functions return a pointer to a static string containing the ASCII representation of *number*. The static string is overwritten by each call to **ecvt**() or **fcvt**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ecvt()	Thread safety	MT-Unsafe race:ecvt
fcvt()	Thread safety	MT-Unsafe race:fcvt

STANDARDS

None.

HISTORY

SVr2; marked as LEGACY in POSIX.1-2001. POSIX.1-2008 removes the specifications of **ecvt**() and **fcvt**(), recommending the use of *sprintf*(3) instead (though *snprintf*(3) may be preferable).

NOTES

Not all locales use a point as the radix character ("decimal point").

ecvt_r, fcvt_r, qecvt_r, qfcvt_r − convert a floating-point number to a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

[[deprecated]] int ecvt_r(double number, int ndigits,
                          int *restrict decpt, int *restrict sign,
                          char *restrict buf, size_t len);
[[deprecated]] int fcvt_r(double number, int ndigits,
                          int *restrict decpt, int *restrict sign,
                          char *restrict buf, size_t len);

[[deprecated]] int qecvt_r(long double number, int ndigits,
                          int *restrict decpt, int *restrict sign,
                          char *restrict buf, size_t len);
[[deprecated]] int qfcvt_r(long double number, int ndigits,
                          int *restrict decpt, int *restrict sign,
                          char *restrict buf, size_t len);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ecvt_r(), **fcvt_r**(), **qecvt_r**(), **qfcvt_r**():

```
/* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE
```

DESCRIPTION

The functions **ecvt_r**(), **fcvt_r**(), **qecvt_r**(), and **qfcvt_r**() are identical to *ecvt*(3), *fcvt*(3), *qecvt*(3), and *qfcvt*(3), respectively, except that they do not return their result in a static buffer, but instead use the supplied *buf* of size *len*. See *ecvt*(3) and *qecvt*(3).

RETURN VALUE

These functions return 0 on success, and −1 otherwise.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

encrypt, setkey, encrypt_r, setkey_r − encrypt 64-bit messages

LIBRARY

Password hashing library (*libcrypt*, *−lcrypt*)

SYNOPSIS

```
#define _XOPEN_SOURCE       /* See feature_test_macros(7) */
#include <unistd.h>

[[deprecated]] void encrypt(char block[64], int edflag);

#define _XOPEN_SOURCE       /* See feature_test_macros(7) */
#include <stdlib.h>

[[deprecated]] void setkey(const char *key);

#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <crypt.h>

[[deprecated]] void setkey_r(const char *key, struct crypt_data *data);
[[deprecated]] void encrypt_r(char *block, int edflag,
                              struct crypt_data *data);
```

DESCRIPTION

These functions encrypt and decrypt 64-bit messages. The **setkey**() function sets the key used by **encrypt**(). The *key* argument used here is an array of 64 bytes, each of which has numerical value 1 or 0. The bytes key[n] where n=8*i-1 are ignored, so that the effective key length is 56 bits.

The **encrypt**() function modifies the passed buffer, encoding if *edflag* is 0, and decoding if 1 is being passed. Like the *key* argument, also *block* is a bit vector representation of the actual value that is encoded. The result is returned in that same vector.

These two functions are not reentrant, that is, the key data is kept in static storage. The functions **setkey_r**() and **encrypt_r**() are the reentrant versions. They use the following structure to hold the key data:

```
struct crypt_data {
    char keysched[16 * 8];
    char sb0[32768];
    char sb1[32768];
    char sb2[32768];
    char sb3[32768];
    char crypt_3_buf[14];
    char current_salt[2];
    long current_saltbits;
    int  direction;
    int  initialized;
};
```

Before calling **setkey_r**() set *data−>initialized* to zero.

RETURN VALUE

These functions do not return any value.

ERRORS

Set *errno* to zero before calling the above functions. On success, *errno* is unchanged.

ENOSYS
The function is not provided. (For example because of former USA export restrictions.)

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
encrypt(), **setkey**()	Thread safety	MT-Unsafe race:crypt
encrypt_r(), **setkey_r**()	Thread safety	MT-Safe

STANDARDS

encrypt()
setkey()
POSIX.1-2008.

encrypt_r()
setkey_r()
None.

HISTORY

Removed in glibc 2.28.

Because they employ the DES block cipher, which is no longer considered secure, these functions were removed from glibc. Applications should switch to a modern cryptography library, such as **libgcrypt**.

encrypt()
setkey()
POSIX.1-2001, SUS, SVr4.

Availability in glibc

See *crypt*(3).

Features in glibc

In glibc 2.2, these functions use the DES algorithm.

EXAMPLES

```
#define _XOPEN_SOURCE
#include <crypt.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(void)
{
    char key[64];
    char orig[9] = "eggplant";
    char buf[64];
    char txt[9];

    for (size_t i = 0; i < 64; i++) {
        key[i] = rand() & 1;
    }

    for (size_t i = 0; i < 8; i++) {
        for (size_t j = 0; j < 8; j++) {
            buf[i * 8 + j] = orig[i] >> j & 1;
        }
        setkey(key);
    }
    printf("Before encrypting: %s\n", orig);

    encrypt(buf, 0);
    for (size_t i = 0; i < 8; i++) {
        for (size_t j = 0, txt[i] = '\0'; j < 8; j++) {
            txt[i] |= buf[i * 8 + j] << j;
        }
        txt[8] = '\0';
    }
    printf("After encrypting:  %s\n", txt);

    encrypt(buf, 1);
    for (size_t i = 0; i < 8; i++) {
```

```
            for (size_t j = 0, txt[i] = '\0'; j < 8; j++) {
                txt[i] |= buf[i * 8 + j] << j;
            }
            txt[8] = '\0';
        }
        printf("After decrypting:  %s\n", txt);
        exit(EXIT_SUCCESS);
    }
```

NAME

etext, edata, end − end of program segments

SYNOPSIS

extern *etext***;**
extern *edata***;**
extern *end***;**

DESCRIPTION

The addresses of these symbols indicate the end of various program segments:

etext This is the first address past the end of the text segment (the program code).

edata This is the first address past the end of the initialized data segment.

end This is the first address past the end of the uninitialized data segment (also known as the BSS segment).

STANDARDS

None.

HISTORY

Although these symbols have long been provided on most UNIX systems, they are not standardized; use with caution.

NOTES

The program must explicitly declare these symbols; they are not defined in any header file.

On some systems the names of these symbols are preceded by underscores, thus: *_etext*, *_edata*, and *_end*. These symbols are also defined for programs compiled on Linux.

At the start of program execution, the program break will be somewhere near *&end* (perhaps at the start of the following page). However, the break will change as memory is allocated via *brk*(2) or *malloc*(3). Use *sbrk*(2) with an argument of zero to find the current value of the program break.

EXAMPLES

When run, the program below produces output such as the following:

```
$ ./a.out
First address past:
    program text (etext)       0x8048568
    initialized data (edata)   0x804a01c
    uninitialized data (end)   0x804a024
```

Program source

```
#include <stdio.h>
#include <stdlib.h>

extern char etext, edata, end; /* The symbols must have some type,
                                  or "gcc -Wall" complains */

int
main(void)
{
    printf("First address past:\n");
    printf("    program text (etext)      %10p\n", &etext);
    printf("    initialized data (edata)  %10p\n", &edata);
    printf("    uninitialized data (end)  %10p\n", &end);

    exit(EXIT_SUCCESS);
}
```

htobe16(), **htole16**(), **be16toh**(), **le16toh**(), **htobe32**(), **htole32**(), **be32toh**(), **le32toh**(), **htobe64**(), **htole64**(), **be64toh**(), **le64toh**():

Since glibc 2.19:
_DEFAULT_SOURCE
In glibc up to and including 2.19:
_BSD_SOURCE

DESCRIPTION

These functions convert the byte encoding of integer values from the byte order that the current CPU (the "host") uses, to and from little-endian and big-endian byte order.

The number, *nn*, in the name of each function indicates the size of integer handled by the function, either 16, 32, or 64 bits.

The functions with names of the form "htobe*nn*" convert from host byte order to big-endian order.

The functions with names of the form "htole*nn*" convert from host byte order to little-endian order.

The functions with names of the form "be*nn*toh" convert from big-endian order to host byte order.

The functions with names of the form "le*nn*toh" convert from little-endian order to host byte order.

VERSIONS

Similar functions are present on the BSDs, where the required header file is <*sys/endian.h*> instead of <*endian.h*>. Unfortunately, NetBSD, FreeBSD, and glibc haven't followed the original OpenBSD naming convention for these functions, whereby the *nn* component always appears at the end of the function name (thus, for example, in NetBSD, FreeBSD, and glibc, the equivalent of OpenBSDs "betoh32" is "be32toh").

STANDARDS

None.

HISTORY

glibc 2.9.

These functions are similar to the older *byteorder*(3) family of functions. For example, **be32toh**() is identical to **ntohl**().

The advantage of the *byteorder*(3) functions is that they are standard functions available on all UNIX systems. On the other hand, the fact that they were designed for use in the context of TCP/IP means that they lack the 64-bit and little-endian variants described in this page.

EXAMPLES

The program below display the results of converting an integer from host byte order to both little-endian and big-endian byte order. Since host byte order is either little-endian or big-endian, only one of these conversions will have an effect. When we run this program on a little-endian system such as x86-32, we see the following:

```
$ ./a.out
x.u32 = 0x44332211
htole32(x.u32) = 0x44332211
htobe32(x.u32) = 0x11223344
```

Program source

```
#include <endian.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    union {
        uint32_t u32;
        uint8_t arr[4];
    } x;

    x.arr[0] = 0x11;  /* Lowest-address byte */
    x.arr[1] = 0x22;
    x.arr[2] = 0x33;
    x.arr[3] = 0x44;  /* Highest-address byte */

    printf("x.u32 = %#x\n", x.u32);
    printf("htole32(x.u32) = %#x\n", htole32(x.u32));
    printf("htobe32(x.u32) = %#x\n", htobe32(x.u32));

    exit(EXIT_SUCCESS);
}
```

NAME

envz_add, envz_entry, envz_get, envz_merge, envz_remove, envz_strip − environment string support

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <envz.h>

error_t envz_add(char **restrict envz, size_t *restrict envz_len,
        const char *restrict name, const char *restrict value);

char *envz_entry(const char *restrict envz, size_t envz_len,
        const char *restrict name);

char *envz_get(const char *restrict envz, size_t envz_len,
        const char *restrict name);

error_t envz_merge(char **restrict envz, size_t *restrict envz_len,
        const char *restrict envz2, size_t envz2_len,
        int override);

void envz_remove(char **restrict envz, size_t *restrict envz_len,
        const char *restrict name);

void envz_strip(char **restrict envz, size_t *restrict envz_len);
```

DESCRIPTION

These functions are glibc-specific.

An argz vector is a pointer to a character buffer together with a length, see *argz_add*(3). An envz vector is a special argz vector, namely one where the strings have the form "name=value". Everything after the first '=' is considered to be the value. If there is no '=', the value is taken to be NULL. (While the value in case of a trailing '=' is the empty string "".)

These functions are for handling envz vectors.

envz_add() adds the string "*name=value*" (in case *value* is non-NULL) or "*name*" (in case *value* is NULL) to the envz vector (**envz*, **envz_len*) and updates **envz* and **envz_len*. If an entry with the same *name* existed, it is removed.

envz_entry() looks for *name* in the envz vector (*envz*, *envz_len*) and returns the entry if found, or NULL if not.

envz_get() looks for *name* in the envz vector (*envz*, *envz_len*) and returns the value if found, or NULL if not. (Note that the value can also be NULL, namely when there is an entry for *name* without '=' sign.)

envz_merge() adds each entry in *envz2* to **envz*, as if with **envz_add**(). If *override* is true, then values in *envz2* will supersede those with the same name in **envz*, otherwise not.

envz_remove() removes the entry for *name* from (**envz*, **envz_len*) if there was one.

envz_strip() removes all entries with value NULL.

RETURN VALUE

All envz functions that do memory allocation have a return type of *error_t* (an integer type), and return 0 for success, and **ENOMEM** if an allocation error occurs.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
envz_add(), **envz_entry**(), **envz_get**(), **envz_merge**(), **envz_remove**(), **envz_strip**()	Thread safety	MT-Safe

STANDARDS

GNU.

EXAMPLES

```
#include <envz.h>
#include <stdio.h>
```

```
#include <stdlib.h>

int
main(int argc, char *argv[], char *envp[])
{
    char    *str;
    size_t  e_len = 0;

    for (size_t i = 0; envp[i] != NULL; i++)
        e_len += strlen(envp[i]) + 1;

    str = envz_entry(*envp, e_len, "HOME");
    printf("%s\n", str);
    str = envz_get(*envp, e_len, "HOME");
    printf("%s\n", str);
    exit(EXIT_SUCCESS);
}
```

NAME

erf, erff, erfl − error function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double erf(double x);
float erff(float x);
long double erfl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

erf():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L || _XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

erff(), **erfl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the error function of *x*, defined as

```
erf(x) = 2/sqrt(pi) * integral from 0 to x of exp(-t*t) dt
```

RETURN VALUE

On success, these functions return the value of the error function of *x*, a value in the range [−1, 1].

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is positive infinity (negative infinity), +1 (−1) is returned.

If *x* is subnormal, a range error occurs, and the return value is 2*x/sqrt(pi).

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result underflow (*x* is subnormal)
An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

These functions do not set *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
erf(), **erff**(), **erfl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD.

SEE ALSO

cerf (3), *erfc*(3), *exp*(3)

NAME

erfc, erfcf, erfcl − complementary error function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double erfc(double x);
float erfcf(float x);
long double erfcl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

erfc():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L || _XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

erfcf(), **erfcl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the complementary error function of *x*, that is, 1.0 − erf(x).

RETURN VALUE

On success, these functions return the complementary error function of *x*, a value in the range [0,2].

If *x* is a NaN, a NaN is returned.

If *x* is +0 or −0, 1 is returned.

If *x* is positive infinity, +0 is returned.

If *x* is negative infinity, +2 is returned.

If the function result underflows and produces an unrepresentable value, the return value is 0.0.

If the function result underflows but produces a representable (i.e., subnormal) value, that value is returned, and a range error occurs.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result underflow (result is subnormal)
An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

These functions do not set *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
erfc(), **erfcf**(), **erfcl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD.

NOTES

The **erfc**(), **erfcf**(), and **erfcl**() functions are provided to avoid the loss accuracy that would occur for the calculation 1-erf(x) for large values of *x* (for which the value of erf(x) approaches 1).

SEE ALSO

cerf (3), *erf*(3), *exp*(3)

NAME

err, verr, errx, verrx, warn, vwarn, warnx, vwarnx − formatted error messages

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <err.h>

[[noreturn]] void err(int eval, const char * fmt, ...);
[[noreturn]] void errx(int eval, const char * fmt, ...);

void warn(const char * fmt, ...);
void warnx(const char * fmt, ...);

#include <stdarg.h>

[[noreturn]] void verr(int eval, const char * fmt, va_list args);
[[noreturn]] void verrx(int eval, const char * fmt, va_list args);

void vwarn(const char * fmt, va_list args);
void vwarnx(const char * fmt, va_list args);
```

DESCRIPTION

The **err**() and **warn**() family of functions display a formatted error message on the standard error output. In all cases, the last component of the program name, a colon character, and a space are output. If the *fmt* argument is not NULL, the *printf*(3)-like formatted error message is output. The output is terminated by a newline character.

The **err**(), **verr**(), **warn**(), and **vwarn**() functions append an error message obtained from *strerror*(3) based on the global variable *errno*, preceded by another colon and space unless the *fmt* argument is NULL.

The **errx**() and **warnx**() functions do not append an error message.

The **err**(), **verr**(), **errx**(), and **verrx**() functions do not return, but exit with the value of the argument *eval*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
err(), **errx**(), **warn**(), **warnx**(), **verr**(), **verrx**(), **vwarn**(), **vwarnx**()	Thread safety	MT-Safe locale

STANDARDS

BSD.

HISTORY

err()
warn() 4.4BSD.

EXAMPLES

Display the current *errno* information string and exit:

```
p = malloc(size);
if (p == NULL)
    err(EXIT_FAILURE, NULL);
fd = open(file_name, O_RDONLY, 0);
if (fd == -1)
    err(EXIT_FAILURE, "%s", file_name);
```

Display an error message and exit:

```
if (tm.tm_hour < START_TIME)
    errx(EXIT_FAILURE, "too early, wait until %s",
            start_time_string);
```

Warn of an error:

```
fd = open(raw_device, O_RDONLY, 0);
```

```
        if (fd == -1)
            warnx("%s: %s: trying the block device",
                    raw_device, strerror(errno));
        fd = open(block_device, O_RDONLY, 0);
        if (fd == -1)
            err(EXIT_FAILURE, "%s", block_device);
```

SEE ALSO

error(3), *exit*(3), *perror*(3), *printf*(3), *strerror*(3)

NAME

errno − number of last error

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <errno.h>

DESCRIPTION

The <*errno.h*> header file defines the integer variable *errno*, which is set by system calls and some library functions in the event of an error to indicate what went wrong.

errno

The value in *errno* is significant only when the return value of the call indicated an error (i.e., −1 from most system calls; −1 or NULL from most library functions); a function that succeeds *is* allowed to change *errno*. The value of *errno* is never set to zero by any system call or library function.

For some system calls and library functions (e.g., *getpriority*(2)), −1 is a valid return on success. In such cases, a successful return can be distinguished from an error return by setting *errno* to zero before the call, and then, if the call returns a status that indicates that an error may have occurred, checking to see if *errno* has a nonzero value.

errno is defined by the ISO C standard to be a modifiable lvalue of type *int*, and must not be explicitly declared; *errno* may be a macro. *errno* is thread-local; setting it in one thread does not affect its value in any other thread.

Error numbers and names

Valid error numbers are all positive numbers. The <*errno.h*> header file defines symbolic names for each of the possible error numbers that may appear in *errno*.

All the error names specified by POSIX.1 must have distinct values, with the exception of **EAGAIN** and **EWOULDBLOCK**, which may be the same. On Linux, these two have the same value on all architectures.

The error numbers that correspond to each symbolic name vary across UNIX systems, and even across different architectures on Linux. Therefore, numeric values are not included as part of the list of error names below. The *perror*(3) and *strerror*(3) functions can be used to convert these names to corresponding textual error messages.

On any particular Linux system, one can obtain a list of all symbolic error names and the corresponding error numbers using the *errno*(1) command (part of the *moreutils* package):

```
$ errno -l
EPERM 1 Operation not permitted
ENOENT 2 No such file or directory
ESRCH 3 No such process
EINTR 4 Interrupted system call
EIO 5 Input/output error
...
```

The *errno*(1) command can also be used to look up individual error numbers and names, and to search for errors using strings from the error description, as in the following examples:

```
$ errno 2
ENOENT 2 No such file or directory
$ errno ESRCH
ESRCH 3 No such process
$ errno -s permission
EACCES 13 Permission denied
```

List of error names

In the list of the symbolic error names below, various names are marked as follows:

POSIX.1-2001

The name is defined by POSIX.1-2001, and is defined in later POSIX.1 versions, unless otherwise indicated.

POSIX.1-2008
The name is defined in POSIX.1-2008, but was not present in earlier POSIX.1 standards.

C99 The name is defined by C99.

Below is a list of the symbolic error names that are defined on Linux:

E2BIG Argument list too long (POSIX.1-2001).

EACCES Permission denied (POSIX.1-2001).

EADDRINUSE Address already in use (POSIX.1-2001).

EADDRNOTAVAIL
Address not available (POSIX.1-2001).

EAFNOSUPPORT
Address family not supported (POSIX.1-2001).

EAGAIN Resource temporarily unavailable (may be the same value as **EWOULDBLOCK**) (POSIX.1-2001).

EALREADY Connection already in progress (POSIX.1-2001).

EBADE Invalid exchange.

EBADF Bad file descriptor (POSIX.1-2001).

EBADFD File descriptor in bad state.

EBADMSG Bad message (POSIX.1-2001).

EBADR Invalid request descriptor.

EBADRQC Invalid request code.

EBADSLT Invalid slot.

EBUSY Device or resource busy (POSIX.1-2001).

ECANCELED Operation canceled (POSIX.1-2001).

ECHILD No child processes (POSIX.1-2001).

ECHRNG Channel number out of range.

ECOMM Communication error on send.

ECONNABORTED
Connection aborted (POSIX.1-2001).

ECONNREFUSED
Connection refused (POSIX.1-2001).

ECONNRESET Connection reset (POSIX.1-2001).

EDEADLK Resource deadlock avoided (POSIX.1-2001).

EDEADLOCK On most architectures, a synonym for **EDEADLK**. On some architectures (e.g., Linux MIPS, PowerPC, SPARC), it is a separate error code "File locking deadlock error".

EDESTADDRREQ
Destination address required (POSIX.1-2001).

EDOM Mathematics argument out of domain of function (POSIX.1, C99).

EDQUOT Disk quota exceeded (POSIX.1-2001).

EEXIST File exists (POSIX.1-2001).

EFAULT Bad address (POSIX.1-2001).

EFBIG File too large (POSIX.1-2001).

EHOSTDOWN Host is down.

EHOSTUNREACH
Host is unreachable (POSIX.1-2001).

EHWPOISON Memory page has hardware error.

EIDRM Identifier removed (POSIX.1-2001).

EILSEQ Invalid or incomplete multibyte or wide character (POSIX.1, C99).

The text shown here is the glibc error description; in POSIX.1, this error is described as "Illegal byte sequence".

EINPROGRESS Operation in progress (POSIX.1-2001).

EINTR Interrupted function call (POSIX.1-2001); see *signal*(7).

EINVAL Invalid argument (POSIX.1-2001).

EIO Input/output error (POSIX.1-2001).

EISCONN Socket is connected (POSIX.1-2001).

EISDIR Is a directory (POSIX.1-2001).

EISNAM Is a named type file.

EKEYEXPIRED Key has expired.

EKEYREJECTED
Key was rejected by service.

EKEYREVOKED
Key has been revoked.

EL2HLT Level 2 halted.

EL2NSYNC Level 2 not synchronized.

EL3HLT Level 3 halted.

EL3RST Level 3 reset.

ELIBACC Cannot access a needed shared library.

ELIBBAD Accessing a corrupted shared library.

ELIBMAX Attempting to link in too many shared libraries.

ELIBSCN .lib section in a.out corrupted

ELIBEXEC Cannot exec a shared library directly.

ELNRNG Link number out of range.

ELOOP Too many levels of symbolic links (POSIX.1-2001).

EMEDIUMTYPE
Wrong medium type.

EMFILE Too many open files (POSIX.1-2001). Commonly caused by exceeding the **RLIMIT_NOFILE** resource limit described in *getrlimit*(2). Can also be caused by exceeding the limit specified in */proc/sys/fs/nr_open*.

EMLINK Too many links (POSIX.1-2001).

EMSGSIZE Message too long (POSIX.1-2001).

EMULTIHOP Multihop attempted (POSIX.1-2001).

ENAMETOOLONG
Filename too long (POSIX.1-2001).

ENETDOWN Network is down (POSIX.1-2001).

ENETRESET Connection aborted by network (POSIX.1-2001).

ENETUNREACH
Network unreachable (POSIX.1-2001).

ENFILE Too many open files in system (POSIX.1-2001). On Linux, this is probably a result of encountering the */proc/sys/fs/file−max* limit (see *proc*(5)).

ENOANO No anode.

ENOBUFS No buffer space available (POSIX.1 (XSI STREAMS option)).

ENODATA The named attribute does not exist, or the process has no access to this attribute; see *xattr*(7).

In POSIX.1-2001 (XSI STREAMS option), this error was described as "No message is available on the STREAM head read queue".

ENODEV No such device (POSIX.1-2001).

ENOENT No such file or directory (POSIX.1-2001).

Typically, this error results when a specified pathname does not exist, or one of the components in the directory prefix of a pathname does not exist, or the specified pathname is a dangling symbolic link.

ENOEXEC Exec format error (POSIX.1-2001).

ENOKEY Required key not available.

ENOLCK No locks available (POSIX.1-2001).

ENOLINK Link has been severed (POSIX.1-2001).

ENOMEDIUM No medium found.

ENOMEM Not enough space/cannot allocate memory (POSIX.1-2001).

ENOMSG No message of the desired type (POSIX.1-2001).

ENONET Machine is not on the network.

ENOPKG Package not installed.

ENOPROTOOPT
Protocol not available (POSIX.1-2001).

ENOSPC No space left on device (POSIX.1-2001).

ENOSR No STREAM resources (POSIX.1 (XSI STREAMS option)).

ENOSTR Not a STREAM (POSIX.1 (XSI STREAMS option)).

ENOSYS Function not implemented (POSIX.1-2001).

ENOTBLK Block device required.

ENOTCONN The socket is not connected (POSIX.1-2001).

ENOTDIR Not a directory (POSIX.1-2001).

ENOTEMPTY Directory not empty (POSIX.1-2001).

ENOTRECOVERABLE
State not recoverable (POSIX.1-2008).

ENOTSOCK Not a socket (POSIX.1-2001).

ENOTSUP Operation not supported (POSIX.1-2001).

ENOTTY Inappropriate I/O control operation (POSIX.1-2001).

ENOTUNIQ Name not unique on network.

ENXIO No such device or address (POSIX.1-2001).

EOPNOTSUPP Operation not supported on socket (POSIX.1-2001).

(**ENOTSUP** and **EOPNOTSUPP** have the same value on Linux, but according to POSIX.1 these error values should be distinct.)

EOVERFLOW Value too large to be stored in data type (POSIX.1-2001).

EOWNERDEAD Owner died (POSIX.1-2008).

EPERM Operation not permitted (POSIX.1-2001).

EPFNOSUPPORT
Protocol family not supported.

EPIPE Broken pipe (POSIX.1-2001).

EPROTO Protocol error (POSIX.1-2001).

EPROTONOSUPPORT
Protocol not supported (POSIX.1-2001).

EPROTOTYPE Protocol wrong type for socket (POSIX.1-2001).

ERANGE Result too large (POSIX.1, C99).

EREMCHG Remote address changed.

EREMOTE Object is remote.

EREMOTEIO Remote I/O error.

ERESTART Interrupted system call should be restarted.

ERFKILL Operation not possible due to RF-kill.

EROFS Read-only filesystem (POSIX.1-2001).

ESHUTDOWN Cannot send after transport endpoint shutdown.

ESPIPE Invalid seek (POSIX.1-2001).

ESOCKTNOSUPPORT
Socket type not supported.

ESRCH No such process (POSIX.1-2001).

ESTALE Stale file handle (POSIX.1-2001).

This error can occur for NFS and for other filesystems.

ESTRPIPE Streams pipe error.

ETIME Timer expired (POSIX.1 (XSI STREAMS option)).

(POSIX.1 says "STREAM *ioctl*(2) timeout".)

ETIMEDOUT Connection timed out (POSIX.1-2001).

ETOOMANYREFS
Too many references: cannot splice.

ETXTBSY Text file busy (POSIX.1-2001).

EUCLEAN Structure needs cleaning.

EUNATCH Protocol driver not attached.

EUSERS Too many users.

EWOULDBLOCK
Operation would block (may be same value as **EAGAIN**) (POSIX.1-2001).

EXDEV Invalid cross-device link (POSIX.1-2001).

EXFULL Exchange full.

NOTES

A common mistake is to do

```
if (somecall() == -1) {
    printf("somecall() failed\n");
    if (errno == ...) { ... }
}
```

where *errno* no longer needs to have the value it had upon return from *somecall*() (i.e., it may have been changed by the *printf*(3)). If the value of *errno* should be preserved across a library call, it must

be saved:

```
if (somecall() == -1) {
    int errsv = errno;
    printf("somecall() failed\n");
    if (errsv == ...) { ... }
}
```

Note that the POSIX threads APIs do *not* set *errno* on error. Instead, on failure they return an error number as the function result. These error numbers have the same meanings as the error numbers returned in *errno* by other APIs.

On some ancient systems, <*errno.h*> was not present or did not declare *errno*, so that it was necessary to declare *errno* manually (i.e., *extern int errno*). **Do not do this**. It long ago ceased to be necessary, and it will cause problems with modern versions of the C library.

errno(1), *err*(3), *error*(3), *perror*(3), *strerror*(3)

NAME

error, error_at_line, error_message_count, error_one_per_line, error_print_progname − glibc error reporting functions

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <error.h>

void error(int status, int errnum, const char * format, ...);
void error_at_line(int status, int errnum, const char * filename,
                   unsigned int linenum, const char * format, ...);

extern unsigned int error_message_count;
extern int error_one_per_line;

extern void (*error_print_progname)(void);
```

DESCRIPTION

error() is a general error-reporting function. It flushes *stdout*, and then outputs to *stderr* the program name, a colon and a space, the message specified by the *printf*(3)-style format string *format*, and, if *errnum* is nonzero, a second colon and a space followed by the string given by *strerror(errnum)*. Any arguments required for *format* should follow *format* in the argument list. The output is terminated by a newline character.

The program name printed by **error**() is the value of the global variable *program_invocation_name*(3). *program_invocation_name* initially has the same value as *main*()'s *argv[0]*. The value of this variable can be modified to change the output of **error**().

If *status* has a nonzero value, then **error**() calls *exit*(3) to terminate the program using the given value as the exit status; otherwise it returns after printing the error message.

The **error_at_line**() function is exactly the same as **error**(), except for the addition of the arguments *filename* and *linenum*. The output produced is as for **error**(), except that after the program name are written: a colon, the value of *filename*, a colon, and the value of *linenum*. The preprocessor values **__LINE__** and **__FILE__** may be useful when calling **error_at_line**(), but other values can also be used. For example, these arguments could refer to a location in an input file.

If the global variable *error_one_per_line* is set nonzero, a sequence of **error_at_line**() calls with the same value of *filename* and *linenum* will result in only one message (the first) being output.

The global variable *error_message_count* counts the number of messages that have been output by **error**() and **error_at_line**().

If the global variable *error_print_progname* is assigned the address of a function (i.e., is not NULL), then that function is called instead of prefixing the message with the program name and colon. The function should print a suitable string to *stderr*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
error()	Thread safety	MT-Safe locale
error_at_line()	Thread safety	MT-Unsafe race: error_at_line/error_one_per_line locale

The internal *error_one_per_line* variable is accessed (without any form of synchronization, but since it's an *int* used once, it should be safe enough) and, if *error_one_per_line* is set nonzero, the internal static variables (not exposed to users) used to hold the last printed filename and line number are accessed and modified without synchronization; the update is not atomic and it occurs before disabling cancelation, so it can be interrupted only after one of the two variables is modified. After that, **error_at_line**() is very much like **error**().

STANDARDS

GNU.

NAME

ether_aton, ether_ntoa, ether_ntohost, ether_hostton, ether_line, ether_ntoa_r, ether_aton_r − Ethernet address manipulation routines

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netinet/ether.h>

char *ether_ntoa(const struct ether_addr *addr);
struct ether_addr *ether_aton(const char *asc);

int ether_ntohost(char *hostname, const struct ether_addr *addr);
int ether_hostton(const char *hostname, struct ether_addr *addr);

int ether_line(const char *line, struct ether_addr *addr,
        char *hostname);

/* GNU extensions */
char *ether_ntoa_r(const struct ether_addr *addr, char *buf);

struct ether_addr *ether_aton_r(const char *asc,
                    struct ether_addr *addr);
```

DESCRIPTION

ether_aton() converts the 48-bit Ethernet host address *asc* from the standard hex-digits-and-colons notation into binary data in network byte order and returns a pointer to it in a statically allocated buffer, which subsequent calls will overwrite. **ether_aton**() returns NULL if the address is invalid.

The **ether_ntoa**() function converts the Ethernet host address *addr* given in network byte order to a string in standard hex-digits-and-colons notation, omitting leading zeros. The string is returned in a statically allocated buffer, which subsequent calls will overwrite.

The **ether_ntohost**() function maps an Ethernet address to the corresponding hostname in */etc/ethers* and returns nonzero if it cannot be found.

The **ether_hostton**() function maps a hostname to the corresponding Ethernet address in */etc/ethers* and returns nonzero if it cannot be found.

The **ether_line**() function parses a line in */etc/ethers* format (ethernet address followed by whitespace followed by hostname; '#' introduces a comment) and returns an address and hostname pair, or nonzero if it cannot be parsed. The buffer pointed to by *hostname* must be sufficiently long, for example, have the same length as *line*.

The functions **ether_ntoa_r**() and **ether_aton_r**() are reentrant thread-safe versions of **ether_ntoa**() and **ether_aton**() respectively, and do not use static buffers.

The structure *ether_addr* is defined in <*net/ethernet.h*> as:

```
struct ether_addr {
    uint8_t ether_addr_octet[6];
}
```

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ether_aton(), **ether_ntoa**()	Thread safety	MT-Unsafe
ether_ntohost(), **ether_hostton**(), **ether_line**(), **ether_ntoa_r**(), **ether_aton_r**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

4.3BSD, SunOS.

BUGS

In glibc 2.2.5 and earlier, the implementation of **ether_line**() is broken.

SEE ALSO

ethers(5)

NAME

euidaccess, eaccess − check effective user's permissions for a file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <unistd.h>

int euidaccess(const char *pathname, int mode);
int eaccess(const char *pathname, int mode);
```

DESCRIPTION

Like *access*(2), **euidaccess**() checks permissions and existence of the file identified by its argument *pathname*. However, whereas *access*(2) performs checks using the real user and group identifiers of the process, **euidaccess**() uses the effective identifiers.

mode is a mask consisting of one or more of **R_OK**, **W_OK**, **X_OK**, and **F_OK**, with the same meanings as for *access*(2).

eaccess() is a synonym for **euidaccess**(), provided for compatibility with some other systems.

RETURN VALUE

On success (all requested permissions granted), zero is returned. On error (at least one bit in *mode* asked for a permission that is denied, or some other error occurred), −1 is returned, and *errno* is set to indicate the error.

ERRORS

As for *access*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
euidaccess(), **eaccess**()	Thread safety	MT-Safe

VERSIONS

Some other systems have an **eaccess**() function.

STANDARDS

None.

HISTORY

eaccess()
: glibc 2.4.

NOTES

Warning: Using this function to check a process's permissions on a file before performing some operation based on that information leads to race conditions: the file permissions may change between the two steps. Generally, it is safer just to attempt the desired operation and handle any permission error that occurs.

This function always dereferences symbolic links. If you need to check the permissions on a symbolic link, use *faccessat*(2) with the flags **AT_EACCESS** and **AT_SYMLINK_NOFOLLOW**.

NAME

execl, execlp, execle, execv, execvp, execvpe − execute a file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

extern char **environ;

int execl(const char *pathname, const char *arg, ...
        /*, (char *) NULL */);
int execlp(const char *file, const char *arg, ...
        /*, (char *) NULL */);
int execle(const char *pathname, const char *arg, ...
        /*, (char *) NULL, char *const envp[] */);
int execv(const char *pathname, char *const argv[]);
int execvp(const char *file, char *const argv[]);
int execvpe(const char *file, char *const argv[], char *const envp[]);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

execvpe():
_GNU_SOURCE

DESCRIPTION

The **exec**() family of functions replaces the current process image with a new process image. The functions described in this manual page are layered on top of *execve*(2). (See the manual page for *execve*(2) for further details about the replacement of the current process image.)

The initial argument for these functions is the name of a file that is to be executed.

The functions can be grouped based on the letters following the "exec" prefix.

l - execl(), execlp(), execle()

The *const char *arg* and subsequent ellipses can be thought of as *arg0*, *arg1*, ..., *argn*. Together they describe a list of one or more pointers to null-terminated strings that represent the argument list available to the executed program. The first argument, by convention, should point to the filename associated with the file being executed. The list of arguments *must* be terminated by a null pointer, and, since these are variadic functions, this pointer must be cast *(char *) NULL*.

By contrast with the 'l' functions, the 'v' functions (below) specify the command-line arguments of the executed program as a vector.

v - execv(), execvp(), execvpe()

The *char *const argv[]* argument is an array of pointers to null-terminated strings that represent the argument list available to the new program. The first argument, by convention, should point to the filename associated with the file being executed. The array of pointers *must* be terminated by a null pointer.

e - execle(), execvpe()

The environment of the new process image is specified via the argument *envp*. The *envp* argument is an array of pointers to null-terminated strings and *must* be terminated by a null pointer.

All other **exec**() functions (which do not include 'e' in the suffix) take the environment for the new process image from the external variable *environ* in the calling process.

p - execlp(), execvp(), execvpe()

These functions duplicate the actions of the shell in searching for an executable file if the specified filename does not contain a slash (/) character. The file is sought in the colon-separated list of directory pathnames specified in the **PATH** environment variable. If this variable isn't defined, the path list defaults to a list that includes the directories returned by *confstr(_CS_PATH)* (which typically returns the value "/bin:/usr/bin") and possibly also the current working directory; see NOTES for further details.

execvpe() searches for the program using the value of **PATH** from the caller's environment, not from the *envp* argument.

If the specified filename includes a slash character, then **PATH** is ignored, and the file at the specified

pathname is executed.

In addition, certain errors are treated specially.

If permission is denied for a file (the attempted *execve*(2) failed with the error **EACCES**), these functions will continue searching the rest of the search path. If no other file is found, however, they will return with *errno* set to **EACCES**.

If the header of a file isn't recognized (the attempted *execve*(2) failed with the error **ENOEXEC**), these functions will execute the shell (*/bin/sh*) with the path of the file as its first argument. (If this attempt fails, no further searching is done.)

All other **exec**() functions (which do not include 'p' in the suffix) take as their first argument a (relative or absolute) pathname that identifies the program to be executed.

RETURN VALUE

The **exec**() functions return only if an error has occurred. The return value is −1, and *errno* is set to indicate the error.

ERRORS

All of these functions may fail and set *errno* for any of the errors specified for *execve*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
execl(), **execle**(), **execv**()	Thread safety	MT-Safe
execlp(), **execvp**(), **execvpe**()	Thread safety	MT-Safe env

VERSIONS

The default search path (used when the environment does not contain the variable **PATH**) shows some variation across systems. It generally includes */bin* and */usr/bin* (in that order) and may also include the current working directory. On some other systems, the current working is included after */bin* and */usr/bin*, as an anti-Trojan-horse measure. The glibc implementation long followed the traditional default where the current working directory is included at the start of the search path. However, some code refactoring during the development of glibc 2.24 caused the current working directory to be dropped altogether from the default search path. This accidental behavior change is considered mildly beneficial, and won't be reverted.

The behavior of **execlp**() and **execvp**() when errors occur while attempting to execute the file is historic practice, but has not traditionally been documented and is not specified by the POSIX standard. BSD (and possibly other systems) do an automatic sleep and retry if **ETXTBSY** is encountered. Linux treats it as a hard error and returns immediately.

Traditionally, the functions **execlp**() and **execvp**() ignored all errors except for the ones described above and **ENOMEM** and **E2BIG**, upon which they returned. They now return if any error other than the ones described above occurs.

STANDARDS

environ
execl()
execlp()
execle()
execv()
execvp()
: POSIX.1-2008.

execvpe()
: GNU.

HISTORY

environ
execl()
execlp()
execle()

execv()
execvp()
POSIX.1-2001.

execvpe()
glibc 2.11.

BUGS

Before glibc 2.24, **execl**() and **execle**() employed *realloc*(3) internally and were consequently not async-signal-safe, in violation of the requirements of POSIX.1. This was fixed in glibc 2.24.

Architecture-specific details

On sparc and sparc64, **execv**() is provided as a system call by the kernel (with the prototype shown above) for compatibility with SunOS. This function is *not* employed by the **execv**() wrapper function on those architectures.

NAME

exit − cause normal process termination

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

[[noreturn]] void exit(int *status***);**

DESCRIPTION

The **exit**() function causes normal process termination and the least significant byte of *status* (i.e., *status & 0xFF*) is returned to the parent (see *wait*(2)).

All functions registered with *atexit*(3) and *on_exit*(3) are called, in the reverse order of their registration. (It is possible for one of these functions to use *atexit*(3) or *on_exit*(3) to register an additional function to be executed during exit processing; the new registration is added to the front of the list of functions that remain to be called.) If one of these functions does not return (e.g., it calls *_exit*(2), or kills itself with a signal), then none of the remaining functions is called, and further exit processing (in particular, flushing of *stdio*(3) streams) is abandoned. If a function has been registered multiple times using *atexit*(3) or *on_exit*(3), then it is called as many times as it was registered.

All open *stdio*(3) streams are flushed and closed. Files created by *tmpfile*(3) are removed.

The C standard specifies two constants, **EXIT_SUCCESS** and **EXIT_FAILURE**, that may be passed to **exit**() to indicate successful or unsuccessful termination, respectively.

RETURN VALUE

The **exit**() function does not return.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
exit()	Thread safety	MT-Unsafe race:exit

The **exit**() function uses a global variable that is not protected, so it is not thread-safe.

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, POSIX.1-2001, SVr4, 4.3BSD.

NOTES

The behavior is undefined if one of the functions registered using *atexit*(3) and *on_exit*(3) calls either **exit**() or *longjmp*(3). Note that a call to *execve*(2) removes registrations created using *atexit*(3) and *on_exit*(3).

The use of **EXIT_SUCCESS** and **EXIT_FAILURE** is slightly more portable (to non-UNIX environments) than the use of 0 and some nonzero value like 1 or −1. In particular, VMS uses a different convention.

BSD has attempted to standardize exit codes (which some C libraries such as the GNU C library have also adopted); see the file *<sysexits.h>*.

After **exit**(), the exit status must be transmitted to the parent process. There are three cases:

- If the parent has set **SA_NOCLDWAIT**, or has set the **SIGCHLD** handler to **SIG_IGN**, the status is discarded and the child dies immediately.
- If the parent was waiting on the child, it is notified of the exit status and the child dies immediately.
- Otherwise, the child becomes a "zombie" process: most of the process resources are recycled, but a slot containing minimal information about the child process (termination status, resource usage statistics) is retained in process table. This allows the parent to subsequently use *waitpid*(2) (or similar) to learn the termination status of the child; at that point the zombie process slot is released.

If the implementation supports the **SIGCHLD** signal, this signal is sent to the parent. If the parent has set **SA_NOCLDWAIT**, it is undefined whether a **SIGCHLD** signal is sent.

Signals sent to other processes

If the exiting process is a session leader and its controlling terminal is the controlling terminal of the session, then each process in the foreground process group of this controlling terminal is sent a **SIGHUP** signal, and the terminal is disassociated from this session, allowing it to be acquired by a new controlling process.

If the exit of the process causes a process group to become orphaned, and if any member of the newly orphaned process group is stopped, then a **SIGHUP** signal followed by a **SIGCONT** signal will be sent to each process in this process group. See *setpgid*(2) for an explanation of orphaned process groups.

Except in the above cases, where the signalled processes may be children of the terminating process, termination of a process does *not* in general cause a signal to be sent to children of that process. However, a process can use the *prctl*(2) **PR_SET_PDEATHSIG** operation to arrange that it receives a signal if its parent terminates.

NAME

exp, expf, expl − base-e exponential function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double exp(double x);
float expf(float x);
long double expl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

expf(), **expl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the value of e (the base of natural logarithms) raised to the power of *x*.

RETURN VALUE

On success, these functions return the exponential value of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity, positive infinity is returned.

If *x* is negative infinity, +0 is returned.

If the result underflows, a range error occurs, and zero is returned.

If the result overflows, a range error occurs, and the functions return +**HUGE_VAL**, +**HUGE_VALF**, or +**HUGE_VALL**, respectively.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error, overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error, underflow
: *errno* is set to **ERANGE**. An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

NAME

expm1, expm1f, expm1l − exponential minus 1

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double expm1(double x);
float expm1f(float x);
long double expm1l(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

expm1():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

expm1f(), **expm1l**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return a value equivalent to

exp(x) − 1

The result is computed in a way that is accurate even if the value of *x* is near zero—a case where *exp(x) − 1* would be inaccurate due to subtraction of two numbers that are nearly equal.

RETURN VALUE

On success, these functions return *exp(x) − 1*.

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is positive infinity, positive infinity is returned.

If *x* is negative infinity, −1 is returned.

If the result overflows, a range error occurs, and the functions return **−HUGE_VAL**, **−HUGE_VALF**, or **−HUGE_VALL**, respectively.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error, overflow
errno is set to **ERANGE** (but see BUGS). An overflow floating-point exception (**FE_OVERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
expm1(), **expm1f**(), **expm1l**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001. BSD.

BUGS

Before glibc 2.17, on certain architectures (e.g., x86, but not x86_64) **expm1**() raised a bogus underflow floating-point exception for some large negative *x* values (where the function result approaches

−1).

Before approximately glibc 2.11, **expm1**() raised a bogus invalid floating-point exception in addition to the expected overflow exception, and returned a NaN instead of positive infinity, for some large positive *x* values.

Before glibc 2.11, the glibc implementation did not set *errno* to **ERANGE** when a range error occurred.

SEE ALSO

NAME

fclose − close a stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

int fclose(FILE *****stream*);**

DESCRIPTION

The **fclose**() function flushes the stream pointed to by *stream* (writing any buffered output data using *fflush*(3)) and closes the underlying file descriptor.

RETURN VALUE

Upon successful completion, 0 is returned. Otherwise, **EOF** is returned and *errno* is set to indicate the error. In either case, any further access (including another call to *fclose*()) to the stream results in undefined behavior.

ERRORS

EBADF

The file descriptor underlying *stream* is not valid.

The **fclose**() function may also fail and set *errno* for any of the errors specified for the routines *close*(2), *write*(2), or *fflush*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fclose()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, POSIX.1-2001.

NOTES

Note that **fclose**() flushes only the user-space buffers provided by the C library. To ensure that the data is physically stored on disk the kernel buffers must be flushed too, for example, with *sync*(2) or *fsync*(2).

SEE ALSO

close(2), *fcloseall*(3), *fflush*(3), *fileno*(3), *fopen*(3), *setbuf*(3)

NAME

fcloseall − close all open streams

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <stdio.h>

int fcloseall(void);
```

DESCRIPTION

The **fcloseall**() function closes all of the calling process's open streams. Buffered output for each stream is written before it is closed (as for *fflush*(3)); buffered input is discarded.

The standard streams, *stdin*, *stdout*, and *stderr* are also closed.

RETURN VALUE

This function returns 0 if all files were successfully closed; on error, **EOF** is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fcloseall()	Thread safety	MT-Unsafe race:streams

The **fcloseall**() function does not lock the streams, so it is not thread-safe.

STANDARDS

GNU.

SEE ALSO

close(2), *fclose*(3), *fflush*(3), *fopen*(3), *setbuf*(3)

NAME

fdim, fdimf, fdiml − positive difference

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double fdim(double x, double y);
float fdimf(float x, float y);
long double fdiml(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fdimf(), **fdiml**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions return the positive difference, max(*x*-*y*,0), between their arguments.

RETURN VALUE

On success, these functions return the positive difference.

If *x* or *y* is a NaN, a NaN is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fdim(), **fdimf**(), **fdiml**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

BUGS

Before glibc 2.24 on certain architectures (e.g., x86, but not x86_64) these functions did not set *errno*.

fmax(3)

NAME

feclearexcept, fegetexceptflag, feraiseexcept, fesetexceptflag, fetestexcept, fegetenv, fegetround, feholdexcept, fesetround, fesetenv, feupdateenv, feenableexcept, fedisableexcept, fegetexcept − floating-point rounding and exception handling

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <fenv.h>

int feclearexcept(int excepts);
int fegetexceptflag(fexcept_t *flagp, int excepts);
int feraiseexcept(int excepts);
int fesetexceptflag(const fexcept_t *flagp, int excepts);
int fetestexcept(int excepts);

int fegetround(void);
int fesetround(int rounding_mode);

int fegetenv(fenv_t *envp);
int feholdexcept(fenv_t *envp);
int fesetenv(const fenv_t *envp);
int feupdateenv(const fenv_t *envp);
```

DESCRIPTION

These eleven functions were defined in C99, and describe the handling of floating-point rounding and exceptions (overflow, zero-divide, etc.).

Exceptions

The *divide-by-zero* exception occurs when an operation on finite numbers produces infinity as exact answer.

The *overflow* exception occurs when a result has to be represented as a floating-point number, but has (much) larger absolute value than the largest (finite) floating-point number that is representable.

The *underflow* exception occurs when a result has to be represented as a floating-point number, but has smaller absolute value than the smallest positive normalized floating-point number (and would lose much accuracy when represented as a denormalized number).

The *inexact* exception occurs when the rounded result of an operation is not equal to the infinite precision result. It may occur whenever *overflow* or *underflow* occurs.

The *invalid* exception occurs when there is no well-defined result for an operation, as for 0/0 or infinity − infinity or sqrt(−1).

Exception handling

Exceptions are represented in two ways: as a single bit (exception present/absent), and these bits correspond in some implementation-defined way with bit positions in an integer, and also as an opaque structure that may contain more information about the exception (perhaps the code address where it occurred).

Each of the macros **FE_DIVBYZERO**, **FE_INEXACT**, **FE_INVALID**, **FE_OVERFLOW**, **FE_UNDERFLOW** is defined when the implementation supports handling of the corresponding exception, and if so then defines the corresponding bit(s), so that one can call exception handling functions, for example, using the integer argument **FE_OVERFLOW**|**FE_UNDERFLOW**. Other exceptions may be supported. The macro **FE_ALL_EXCEPT** is the bitwise OR of all bits corresponding to supported exceptions.

The **feclearexcept**() function clears the supported exceptions represented by the bits in its argument.

The **fegetexceptflag**() function stores a representation of the state of the exception flags represented by the argument *excepts* in the opaque object **flagp*.

The **feraiseexcept**() function raises the supported exceptions represented by the bits in *excepts*.

The **fesetexceptflag**() function sets the complete status for the exceptions represented by *excepts* to the value **flagp*. This value must have been obtained by an earlier call of **fegetexceptflag**() with a last argument that contained all bits in *excepts*.

The **fetestexcept**() function returns a word in which the bits are set that were set in the argument *excepts* and for which the corresponding exception is currently set.

Rounding mode

The rounding mode determines how the result of floating-point operations is treated when the result cannot be exactly represented in the significand. Various rounding modes may be provided: round to nearest (the default), round up (toward positive infinity), round down (toward negative infinity), and round toward zero.

Each of the macros **FE_TONEAREST**, **FE_UPWARD**, **FE_DOWNWARD**, and **FE_TOWARDZERO** is defined when the implementation supports getting and setting the corresponding rounding direction.

The **fegetround**() function returns the macro corresponding to the current rounding mode.

The **fesetround**() function sets the rounding mode as specified by its argument and returns zero when it was successful.

C99 and POSIX.1-2008 specify an identifier, **FLT_ROUNDS**, defined in <*float.h*>, which indicates the implementation-defined rounding behavior for floating-point addition. This identifier has one of the following values:

−1 The rounding mode is not determinable.

0 Rounding is toward 0.

1 Rounding is toward nearest number.

2 Rounding is toward positive infinity.

3 Rounding is toward negative infinity.

Other values represent machine-dependent, nonstandard rounding modes.

The value of **FLT_ROUNDS** should reflect the current rounding mode as set by **fesetround**() (but see BUGS).

Floating-point environment

The entire floating-point environment, including control modes and status flags, can be handled as one opaque object, of type *fenv_t*. The default environment is denoted by **FE_DFL_ENV** (of type *const fenv_t **). This is the environment setup at program start and it is defined by ISO C to have round to nearest, all exceptions cleared and a nonstop (continue on exceptions) mode.

The **fegetenv**() function saves the current floating-point environment in the object **envp*.

The **feholdexcept**() function does the same, then clears all exception flags, and sets a nonstop (continue on exceptions) mode, if available. It returns zero when successful.

The **fesetenv**() function restores the floating-point environment from the object **envp*. This object must be known to be valid, for example, the result of a call to **fegetenv**() or **feholdexcept**() or equal to **FE_DFL_ENV**. This call does not raise exceptions.

The **feupdateenv**() function installs the floating-point environment represented by the object **envp*, except that currently raised exceptions are not cleared. After calling this function, the raised exceptions will be a bitwise OR of those previously set with those in **envp*. As before, the object **envp* must be known to be valid.

RETURN VALUE

These functions return zero on success and nonzero if an error occurred.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
feclearexcept(), **fegetexceptflag**(), **feraiseexcept**(), **fesetexceptflag**(), **fetestexcept**(), **fegetround**(), **fesetround**(), **fegetenv**(), **feholdexcept**(), **fesetenv**(), **feupdateenv**(), **feenableexcept**(), **fedisableexcept**(), **fegetexcept**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008, IEC 60559 (IEC 559:1989), ANSI/IEEE 854.

HISTORY

C99, POSIX.1-2001. glibc 2.1.

NOTES

glibc notes

If possible, the GNU C Library defines a macro **FE_NOMASK_ENV** which represents an environment where every exception raised causes a trap to occur. You can test for this macro using **#ifdef**. It is defined only if **_GNU_SOURCE** is defined. The C99 standard does not define a way to set individual bits in the floating-point mask, for example, to trap on specific flags. Since glibc 2.2, glibc supports the functions **feenableexcept**() and **fedisableexcept**() to set individual floating-point traps, and **fegetexcept**() to query the state.

```
#define _GNU_SOURCE       /* See feature_test_macros(7) */
#include <fenv.h>

int feenableexcept(int excepts);
int fedisableexcept(int excepts);
int fegetexcept(void);
```

The **feenableexcept**() and **fedisableexcept**() functions enable (disable) traps for each of the exceptions represented by *excepts* and return the previous set of enabled exceptions when successful, and −1 otherwise. The **fegetexcept**() function returns the set of all currently enabled exceptions.

BUGS

C99 specifies that the value of **FLT_ROUNDS** should reflect changes to the current rounding mode, as set by **fesetround**(). Currently, this does not occur: **FLT_ROUNDS** always has the value 1.

math_error(7)

NAME

clearerr, feof, ferror − check and reset stream status

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

void clearerr(FILE *stream);
int feof(FILE *stream);
int ferror(FILE *stream);
```

DESCRIPTION

The function **clearerr**() clears the end-of-file and error indicators for the stream pointed to by *stream*.

The function **feof**() tests the end-of-file indicator for the stream pointed to by *stream*, returning nonzero if it is set. The end-of-file indicator can be cleared only by the function **clearerr**().

The function **ferror**() tests the error indicator for the stream pointed to by *stream*, returning nonzero if it is set. The error indicator can be reset only by the **clearerr**() function.

For nonlocking counterparts, see *unlocked_stdio*(3).

RETURN VALUE

The **feof**() function returns nonzero if the end-of-file indicator is set for *stream*; otherwise, it returns zero.

The **ferror**() function returns nonzero if the error indicator is set for *stream*; otherwise, it returns zero.

ERRORS

These functions should not fail and do not set *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
clearerr(), **feof**(), **ferror**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, POSIX.1-2001.

NOTES

POSIX.1-2008 specifies that these functions shall not change the value of *errno* if *stream* is valid.

CAVEATS

Normally, programs should read the return value of an input function, such as *fgetc*(3), before using functions of the *feof*(3) family. Only when the function returned the sentinel value **EOF** it makes sense to distinguish between the end of a file or an error with *feof*(3) or *ferror*(3).

NAME

fexecve − execute program specified via file descriptor

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int fexecve(int *fd***, char *const** *argv***[], char *const** *envp***[]);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fexecve():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

fexecve() performs the same task as *execve*(2), with the difference that the file to be executed is specified via a file descriptor, *fd*, rather than via a pathname. The file descriptor *fd* must be opened read-only (**O_RDONLY**) or with the **O_PATH** flag and the caller must have permission to execute the file that it refers to.

RETURN VALUE

A successful call to **fexecve**() never returns. On error, the function does return, with a result value of −1, and *errno* is set to indicate the error.

ERRORS

Errors are as for *execve*(2), with the following additions:

EINVAL
fd is not a valid file descriptor, or *argv* is NULL, or *envp* is NULL.

ENOENT
The close-on-exec flag is set on *fd*, and *fd* refers to a script. See BUGS.

ENOSYS
The kernel does not provide the *execveat*(2) system call, and the */proc* filesystem could not be accessed.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fexecve()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.3.2.

On Linux with glibc versions 2.26 and earlier, **fexecve**() is implemented using the *proc*(5) filesystem, so */proc* needs to be mounted and available at the time of the call. Since glibc 2.27, if the underlying kernel supports the *execveat*(2) system call, then **fexecve**() is implemented using that system call, with the benefit that */proc* does not need to be mounted.

NOTES

The idea behind **fexecve**() is to allow the caller to verify (checksum) the contents of an executable before executing it. Simply opening the file, checksumming the contents, and then doing an *execve*(2) would not suffice, since, between the two steps, the filename, or a directory prefix of the pathname, could have been exchanged (by, for example, modifying the target of a symbolic link). **fexecve**() does not mitigate the problem that the *contents* of a file could be changed between the checksumming and the call to **fexecve**(); for that, the solution is to ensure that the permissions on the file prevent it from being modified by malicious users.

The natural idiom when using **fexecve**() is to set the close-on-exec flag on *fd*, so that the file descriptor does not leak through to the program that is executed. This approach is natural for two reasons. First,

it prevents file descriptors being consumed unnecessarily. (The executed program normally has no need of a file descriptor that refers to the program itself.) Second, if **fexecve**() is used recursively, employing the close-on-exec flag prevents the file descriptor exhaustion that would result from the fact that each step in the recursion would cause one more file descriptor to be passed to the new program. (But see BUGS.)

BUGS

If *fd* refers to a script (i.e., it is an executable text file that names a script interpreter with a first line that begins with the characters *#!*) and the close-on-exec flag has been set for *fd*, then **fexecve**() fails with the error **ENOENT**. This error occurs because, by the time the script interpreter is executed, *fd* has already been closed because of the close-on-exec flag. Thus, the close-on-exec flag can't be set on *fd* if it refers to a script, leading to the problems described in NOTES.

SEE ALSO

execve(2), *execveat*(2)

NAME

fflush − flush a stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int fflush(FILE *_Nullable stream);
```

DESCRIPTION

For output streams, **fflush**() forces a write of all user-space buffered data for the given output or update *stream* via the stream's underlying write function.

For input streams associated with seekable files (e.g., disk files, but not pipes or terminals), **fflush**() discards any buffered data that has been fetched from the underlying file, but has not been consumed by the application.

The open status of the stream is unaffected.

If the *stream* argument is NULL, **fflush**() flushes *all* open output streams.

For a nonlocking counterpart, see *unlocked_stdio*(3).

RETURN VALUE

Upon successful completion 0 is returned. Otherwise, **EOF** is returned and *errno* is set to indicate the error.

ERRORS

EBADF
: *stream* is not an open stream, or is not open for writing.

The function **fflush**() may also fail and set *errno* for any of the errors specified for *write*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fflush()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, POSIX.1-2001, POSIX.1-2008.

POSIX.1-2001 did not specify the behavior for flushing of input streams, but the behavior is specified in POSIX.1-2008.

NOTES

Note that **fflush**() flushes only the user-space buffers provided by the C library. To ensure that the data is physically stored on disk the kernel buffers must be flushed too, for example, with *sync*(2) or *fsync*(2).

SEE ALSO

fsync(2), *sync*(2), *write*(2), *fclose*(3), *fileno*(3), *fopen*(3), *fpurge*(3), *setbuf*(3), *unlocked_stdio*(3)

NAME

ffs, ffsl, ffsll − find first bit set in a word

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <strings.h>

int ffs(int i);
int ffsl(long i);
int ffsll(long long i);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ffs():
Since glibc 2.12:
_XOPEN_SOURCE >= 700
|| ! (_POSIX_C_SOURCE >= 200809L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
Before glibc 2.12:
none

ffsl(), **ffsll**():
Since glibc 2.27:
_DEFAULT_SOURCE
Before glibc 2.27:
_GNU_SOURCE

DESCRIPTION

The **ffs**() function returns the position of the first (least significant) bit set in the word *i*. The least significant bit is position 1 and the most significant position is, for example, 32 or 64. The functions **ffsll**() and **ffsl**() do the same but take arguments of possibly different size.

RETURN VALUE

These functions return the position of the first bit set, or 0 if no bits are set in *i*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ffs(), **ffsl**(), **ffsll**()	Thread safety	MT-Safe

STANDARDS

ffs() POSIX.1-2001, POSIX.1-2008, 4.3BSD.

ffsl()
ffsll() GNU.

SEE ALSO

memchr(3)

NAME

fgetc, fgets, getc, getchar, ungetc − input of characters and strings

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int fgetc(FILE *stream);
int getc(FILE *stream);
int getchar(void);

char *fgets(char s[restrict .size], int size, FILE *restrict stream);

int ungetc(int c, FILE *stream);
```

DESCRIPTION

fgetc() reads the next character from *stream* and returns it as an *unsigned char* cast to an *int*, or **EOF** on end of file or error.

getc() is equivalent to **fgetc**() except that it may be implemented as a macro which evaluates *stream* more than once.

getchar() is equivalent to **getc(***stdin***)**.

fgets() reads in at most one less than *size* characters from *stream* and stores them into the buffer pointed to by *s*. Reading stops after an **EOF** or a newline. If a newline is read, it is stored into the buffer. A terminating null byte ('\0') is stored after the last character in the buffer.

ungetc() pushes *c* back to *stream*, cast to *unsigned char*, where it is available for subsequent read operations. Pushed-back characters will be returned in reverse order; only one pushback is guaranteed.

Calls to the functions described here can be mixed with each other and with calls to other input functions from the *stdio* library for the same input stream.

For nonlocking counterparts, see *unlocked_stdio*(3).

RETURN VALUE

fgetc(), **getc**(), and **getchar**() return the character read as an *unsigned char* cast to an *int* or **EOF** on end of file or error.

fgets() returns *s* on success, and NULL on error or when end of file occurs while no characters have been read.

ungetc() returns *c* on success, or **EOF** on error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fgetc(), **fgets**(), **getc**(), **getchar**(), **ungetc**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89.

NOTES

It is not advisable to mix calls to input functions from the *stdio* library with low-level calls to *read*(2) for the file descriptor associated with the input stream; the results will be undefined and very probably not what you want.

SEE ALSO

NAME

fgetgrent − get group file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <sys/types.h>
#include <grp.h>

struct group *fgetgrent(FILE *stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fgetgrent():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

The **fgetgrent**() function returns a pointer to a structure containing the group information from the file referred to by *stream*. The first time it is called it returns the first entry; thereafter, it returns successive entries. The file referred to by *stream* must have the same format as */etc/group* (see *group*(5)).

The *group* structure is defined in <*grp.h*> as follows:

```
struct group {
    char   *gr_name;        /* group name */
    char   *gr_passwd;      /* group password */
    gid_t   gr_gid;         /* group ID */
    char  **gr_mem;         /* NULL-terminated array of pointers
                               to names of group members */
};
```

RETURN VALUE

The **fgetgrent**() function returns a pointer to a *group* structure, or NULL if there are no more entries or an error occurs. In the event of an error, *errno* is set to indicate the error.

ERRORS

ENOMEM
Insufficient memory to allocate *group* structure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

fgetpwent − get password file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <sys/types.h>
#include <pwd.h>

struct passwd *fgetpwent(FILE *stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fgetpwent():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

The **fgetpwent**() function returns a pointer to a structure containing the broken out fields of a line in the file *stream*. The first time it is called it returns the first entry; thereafter, it returns successive entries. The file referred to by *stream* must have the same format as */etc/passwd* (see *passwd*(5)).

The *passwd* structure is defined in <*pwd.h*> as follows:

```
struct passwd {
    char   *pw_name;       /* username */
    char   *pw_passwd;     /* user password */
    uid_t   pw_uid;        /* user ID */
    gid_t   pw_gid;        /* group ID */
    char   *pw_gecos;      /* real name */
    char   *pw_dir;        /* home directory */
    char   *pw_shell;      /* shell program */
};
```

RETURN VALUE

The **fgetpwent**() function returns a pointer to a *passwd* structure, or NULL if there are no more entries or an error occurs. In the event of an error, *errno* is set to indicate the error.

ERRORS

ENOMEM
Insufficient memory to allocate *passwd* structure.

FILES

/etc/passwd
password database file

ATTRIBUTES

NAME

fgetwc, getwc − read a wide character from a FILE stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

wint_t fgetwc(FILE *stream);
wint_t getwc(FILE *stream);
```

DESCRIPTION

The **fgetwc**() function is the wide-character equivalent of the *fgetc*(3) function. It reads a wide character from *stream* and returns it. If the end of stream is reached, or if *ferror(stream)* becomes true, it returns **WEOF**. If a wide-character conversion error occurs, it sets *errno* to **EILSEQ** and returns **WEOF**.

The **getwc**() function or macro functions identically to **fgetwc**(). It may be implemented as a macro, and may evaluate its argument more than once. There is no reason ever to use it.

For nonlocking counterparts, see *unlocked_stdio*(3).

RETURN VALUE

On success, **fgetwc**() returns the next wide-character from the stream. Otherwise, **WEOF** is returned, and *errno* is set to indicate the error.

ERRORS

Apart from the usual ones, there is

EILSEQ
: The data obtained from the input stream does not form a valid character.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fgetwc(), **getwc**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **fgetwc**() depends on the **LC_CTYPE** category of the current locale.

In the absence of additional information passed to the *fopen*(3) call, it is reasonable to expect that **fgetwc**() will actually read a multibyte sequence from the stream and then convert it to a wide character.

SEE ALSO

fgetws(3), *fputwc*(3), *ungetwc*(3), *unlocked_stdio*(3)

NAME

fgetws − read a wide-character string from a FILE stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

wchar_t *fgetws(wchar_t *ws***[restrict .***n***], int** *n***, FILE *restrict** *stream***);**

DESCRIPTION

The **fgetws**() function is the wide-character equivalent of the *fgets*(3) function. It reads a string of at most *n−1* wide characters into the wide-character array pointed to by *ws*, and adds a terminating null wide character (L'\0'). It stops reading wide characters after it has encountered and stored a newline wide character. It also stops when end of stream is reached.

The programmer must ensure that there is room for at least *n* wide characters at *ws*.

For a nonlocking counterpart, see *unlocked_stdio*(3).

RETURN VALUE

The **fgetws**() function, if successful, returns *ws*. If end of stream was already reached or if an error occurred, it returns NULL.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fgetws()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **fgetws**() depends on the **LC_CTYPE** category of the current locale.

In the absence of additional information passed to the *fopen*(3) call, it is reasonable to expect that **fgetws**() will actually read a multibyte string from the stream and then convert it to a wide-character string.

This function is unreliable, because it does not permit to deal properly with null wide characters that may be present in the input.

SEE ALSO

NAME

fileno − obtain file descriptor of a stdio stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

int fileno(FILE *_stream_);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fileno():
_POSIX_C_SOURCE

DESCRIPTION

The function **fileno**() examines the argument *stream* and returns the integer file descriptor used to implement this stream. The file descriptor is still owned by *stream* and will be closed when *fclose*(3) is called. Duplicate the file descriptor with *dup*(2) before passing it to code that might close it.

For the nonlocking counterpart, see *unlocked_stdio*(3).

RETURN VALUE

On success, **fileno**() returns the file descriptor associated with *stream*. On failure, −1 is returned and *errno* is set to indicate the error.

ERRORS

EBADF
stream is not associated with a file.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

finite, finitef, finitel, isinf, isinff, isinfl, isnan, isnanf, isnanl − BSD floating-point classification functions

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

int finite(double x);
int finitef(float x);
int finitel(long double x);

int isinf(double x);
int isinff(float x);
int isinfl(long double x);

int isnan(double x);
int isnanf(float x);
int isnanl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

finite(), **finitef**(), **finitel**():
/* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

isinf():
_XOPEN_SOURCE >= 600 || _ISOC99_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

isinff(), **isinfl**():
/* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

isnan():
_XOPEN_SOURCE || _ISOC99_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

isnanf(), **isnanl**():
_XOPEN_SOURCE >= 600
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **finite**(), **finitef**(), and **finitel**() functions return a nonzero value if *x* is neither infinite nor a "not-a-number" (NaN) value, and 0 otherwise.

The **isnan**(), **isnanf**(), and **isnanl**() functions return a nonzero value if *x* is a NaN value, and 0 otherwise.

The **isinf**(), **isinff**(), and **isinfl**() functions return 1 if *x* is positive infinity, −1 if *x* is negative infinity, and 0 otherwise.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
finite(), **finitef**(), **finitel**(), **isinf**(), **isinff**(), **isinfl**(), **isnan**(), **isnanf**(), **isnanl**()	Thread safety	MT-Safe

NOTES

Note that these functions are obsolete. C99 defines macros **isfinite**(), **isinf**(), and **isnan**() (for all types) replacing them. Further note that the C99 **isinf**() has weaker guarantees on the return value. See *fpclassify*(3).

NAME

flockfile, ftrylockfile, funlockfile − lock FILE for stdio

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

void flockfile(FILE *filehandle);
int ftrylockfile(FILE *filehandle);
void funlockfile(FILE *filehandle);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:

```
/* Since glibc 2.24: */ _POSIX_C_SOURCE >= 199309L
    || /* glibc <= 2.23: */ _POSIX_C_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

DESCRIPTION

The stdio functions are thread-safe. This is achieved by assigning to each *FILE* object a lockcount and (if the lockcount is nonzero) an owning thread. For each library call, these functions wait until the *FILE* object is no longer locked by a different thread, then lock it, do the requested I/O, and unlock the object again.

(Note: this locking has nothing to do with the file locking done by functions like *flock*(2) and *lockf*(3).)

All this is invisible to the C-programmer, but there may be two reasons to wish for more detailed control. On the one hand, maybe a series of I/O actions by one thread belongs together, and should not be interrupted by the I/O of some other thread. On the other hand, maybe the locking overhead should be avoided for greater efficiency.

To this end, a thread can explicitly lock the *FILE* object, then do its series of I/O actions, then unlock. This prevents other threads from coming in between. If the reason for doing this was to achieve greater efficiency, one does the I/O with the nonlocking versions of the stdio functions: with *getc_unlocked*(3) and *putc_unlocked*(3) instead of *getc*(3) and *putc*(3).

The **flockfile**() function waits for **filehandle* to be no longer locked by a different thread, then makes the current thread owner of **filehandle*, and increments the lockcount.

The **funlockfile**() function decrements the lock count.

The **ftrylockfile**() function is a nonblocking version of **flockfile**(). It does nothing in case some other thread owns **filehandle*, and it obtains ownership and increments the lockcount otherwise.

RETURN VALUE

The **ftrylockfile**() function returns zero for success (the lock was obtained), and nonzero for failure.

ERRORS

None.

ATTRIBUTES

NAME

floor, floorf, floorl − largest integral value not greater than argument

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double floor(double x);
float floorf(float x);
long double floorl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

floorf(), **floorl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the largest integral value that is not greater than *x*.

For example, *floor(0.5)* is 0.0, and *floor(−0.5)* is −1.0.

RETURN VALUE

These functions return the floor of *x*.

If *x* is integral, +0, −0, NaN, or an infinity, *x* itself is returned.

ERRORS

No errors occur. POSIX.1-2001 documents a range error for overflows, but see NOTES.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
floor(), **floorf**(), **floorl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

SUSv2 and POSIX.1-2001 contain text about overflow (which might set *errno* to **ERANGE**, or raise an **FE_OVERFLOW** exception). In practice, the result cannot overflow on any current machine, so this error-handling stuff is just nonsense. (More precisely, overflow can happen only when the maximum value of the exponent is smaller than the number of mantissa bits. For the IEEE-754 standard 32-bit and 64-bit floating-point numbers the maximum value of the exponent is 127 (respectively, 1023), and the number of mantissa bits including the implicit bit is 24 (respectively, 53).)

NAME

fma, fmaf, fmal − floating-point multiply and add

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <math.h>

double fma(double *x***, double** *y***, double** *z***);**
float fmaf(float *x***, float** *y***, float** *z***);**
long double fmal(long double *x***, long double** *y***, long double** *z***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fma(), **fmaf**(), **fmal**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions compute *x* * *y* + *z*. The result is rounded as one ternary operation according to the current rounding mode (see *fenv*(3)).

RETURN VALUE

These functions return the value of *x* * *y* + *z*, rounded as one ternary operation.

If *x* or *y* is a NaN, a NaN is returned.

If *x* times *y* is an exact infinity, and *z* is an infinity with the opposite sign, a domain error occurs, and a NaN is returned.

If one of *x* or *y* is an infinity, the other is 0, and *z* is not a NaN, a domain error occurs, and a NaN is returned.

If one of *x* or *y* is an infinity, and the other is 0, and *z* is a NaN, a domain error occurs, and a NaN is returned.

If *x* times *y* is not an infinity times zero (or vice versa), and *z* is a NaN, a NaN is returned.

If the result overflows, a range error occurs, and an infinity with the correct sign is returned.

If the result underflows, a range error occurs, and a signed 0 is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* * *y* + *z*, or *x* * *y* is invalid and *z* is not a NaN
: An invalid floating-point exception (**FE_INVALID**) is raised.

Range error: result overflow
: An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error: result underflow
: An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

These functions do not set *errno*.

NAME

fmemopen − open memory as stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

FILE *fmemopen(void *buf* **[.***size***], size_t** *size***, const char *** *mode***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fmemopen():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **fmemopen**() function opens a stream that permits the access specified by *mode*. The stream allows I/O to be performed on the string or memory buffer pointed to by *buf*.

The *mode* argument specifies the semantics of I/O on the stream, and is one of the following:

r The stream is opened for reading.

w The stream is opened for writing.

a Append; open the stream for writing, with the initial buffer position set to the first null byte.

r+ Open the stream for reading and writing.

w+ Open the stream for reading and writing. The buffer contents are truncated (i.e., '\0' is placed in the first byte of the buffer).

a+ Append; open the stream for reading and writing, with the initial buffer position set to the first null byte.

The stream maintains the notion of a current position, the location where the next I/O operation will be performed. The current position is implicitly updated by I/O operations. It can be explicitly updated using *fseek*(3), and determined using *ftell*(3). In all modes other than append, the initial position is set to the start of the buffer. In append mode, if no null byte is found within the buffer, then the initial position is *size+1*.

If *buf* is specified as NULL, then **fmemopen**() allocates a buffer of *size* bytes. This is useful for an application that wants to write data to a temporary buffer and then read it back again. The initial position is set to the start of the buffer. The buffer is automatically freed when the stream is closed. Note that the caller has no way to obtain a pointer to the temporary buffer allocated by this call (but see *open_memstream*(3)).

If *buf* is not NULL, then it should point to a buffer of at least *size* bytes allocated by the caller.

When a stream that has been opened for writing is flushed (**fflush**(3)) or closed (**fclose**(3)), a null byte is written at the end of the buffer if there is space. The caller should ensure that an extra byte is available in the buffer (and that *size* counts that byte) to allow for this.

In a stream opened for reading, null bytes ('\0') in the buffer do not cause read operations to return an end-of-file indication. A read from the buffer will indicate end-of-file only when the current buffer position advances *size* bytes past the start of the buffer.

Write operations take place either at the current position (for modes other than append), or at the current size of the stream (for append modes).

Attempts to write more than *size* bytes to the buffer result in an error. By default, such errors will be visible (by the absence of data) only when the *stdio* buffer is flushed. Disabling buffering with the following call may be useful to detect errors at the time of an output operation:

```
setbuf(stream, NULL);
```

RETURN VALUE

Upon successful completion, **fmemopen**() returns a *FILE* pointer. Otherwise, NULL is returned and *errno* is set to indicate the error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fmemopen(),	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 1.0.x. POSIX.1-2008.

POSIX.1-2008 specifies that 'b' in *mode* shall be ignored. However, Technical Corrigendum 1 adjusts the standard to allow implementation-specific treatment for this case, thus permitting the glibc treatment of 'b'.

With glibc 2.22, binary mode (see below) was removed, many longstanding bugs in the implementation of **fmemopen**() were fixed, and a new versioned symbol was created for this interface.

Binary mode

From glibc 2.9 to glibc 2.21, the glibc implementation of **fmemopen**() supported a "binary" mode, enabled by specifying the letter 'b' as the second character in *mode*. In this mode, writes don't implicitly add a terminating null byte, and *fseek*(3) **SEEK_END** is relative to the end of the buffer (i.e., the value specified by the *size* argument), rather than the current string length.

An API bug afflicted the implementation of binary mode: to specify binary mode, the 'b' must be the *second* character in *mode*. Thus, for example, "wb+" has the desired effect, but "w+b" does not. This is inconsistent with the treatment of *mode* by *fopen*(3).

Binary mode was removed in glibc 2.22; a 'b' specified in *mode* has no effect.

NOTES

There is no file descriptor associated with the file stream returned by this function (i.e., *fileno*(3) will return an error if called on the returned stream).

BUGS

Before glibc 2.22, if *size* is specified as zero, **fmemopen**() fails with the error **EINVAL**. It would be more consistent if this case successfully created a stream that then returned end-of-file on the first attempt at reading; since glibc 2.22, the glibc implementation provides that behavior.

Before glibc 2.22, specifying append mode ("a" or "a+") for **fmemopen**() sets the initial buffer position to the first null byte, but (if the current position is reset to a location other than the end of the stream) does not force subsequent writes to append at the end of the stream. This bug is fixed in glibc 2.22.

Before glibc 2.22, if the *mode* argument to **fmemopen**() specifies append ("a" or "a+"), and the *size* argument does not cover a null byte in *buf*, then, according to POSIX.1-2008, the initial buffer position should be set to the next byte after the end of the buffer. However, in this case the glibc **fmemopen**() sets the buffer position to −1. This bug is fixed in glibc 2.22.

Before glibc 2.22, when a call to *fseek*(3) with a *whence* value of **SEEK_END** was performed on a stream created by **fmemopen**(), the *offset* was *subtracted* from the end-of-stream position, instead of being added. This bug is fixed in glibc 2.22.

The glibc 2.9 addition of "binary" mode for **fmemopen**() silently changed the ABI: previously, **fmemopen**() ignored 'b' in *mode*.

EXAMPLES

The program below uses **fmemopen**() to open an input buffer, and *open_memstream*(3) to open a dynamically sized output buffer. The program scans its input string (taken from the program's first command-line argument) reading integers, and writes the squares of these integers to the output buffer. An example of the output produced by this program is the following:

```
$ ./a.out '1 23 43'
size=11; ptr=1 529 1849
```

Program source

```
#define _GNU_SOURCE
#include <err.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(int argc, char *argv[])
{
    FILE *out, *in;
    int v, s;
    size_t size;
    char *ptr;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s '<num>...'\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    in = fmemopen(argv[1], strlen(argv[1]), "r");
    if (in == NULL)
        err(EXIT_FAILURE, "fmemopen");

    out = open_memstream(&ptr, &size);
    if (out == NULL)
        err(EXIT_FAILURE, "open_memstream");

    for (;;) {
        s = fscanf(in, "%d", &v);
        if (s <= 0)
            break;

        s = fprintf(out, "%d ", v * v);
        if (s == -1)
            err(EXIT_FAILURE, "fprintf");
    }

    fclose(in);
    fclose(out);

    printf("size=%zu; ptr=%s\n", size, ptr);

    free(ptr);
    exit(EXIT_SUCCESS);
}
```

NAME

fmod, fmodf, fmodl − floating-point remainder function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double fmod(double x, double y);
float fmodf(float x, float y);
long double fmodl(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fmodf(), **fmodl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions compute the floating-point remainder of dividing *x* by *y*. The return value is *x* − *n* * *y*, where *n* is the quotient of *x* / *y*, rounded toward zero to an integer.

To obtain the modulus, more specifically, the Least Positive Residue, you will need to adjust the result from fmod like so:

```
z = fmod(x, y);
if (z < 0)
        z += y;
```

An alternate way to express this is with *fmod(fmod(x, y) + y, y)*, but the second **fmod**() usually costs way more than the one branch.

RETURN VALUE

On success, these functions return the value *x* − *n***y*, for some integer *n*, such that the returned value has the same sign as *x* and a magnitude less than the magnitude of *y*.

If *x* or *y* is a NaN, a NaN is returned.

If *x* is an infinity, a domain error occurs, and a NaN is returned.

If *y* is zero, a domain error occurs, and a NaN is returned.

If *x* is +0 (−0), and *y* is not zero, +0 (−0) is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

Domain error: *y* is zero
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fmod(), **fmodf**(), **fmodl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

BUGS

Before glibc 2.10, the glibc implementation did not set *errno* to **EDOM** when a domain error occurred for an infinite *x*.

EXAMPLES

The call *fmod(372, 360)* returns 348.

The call *fmod(-372, 360)* returns -12.

The call *fmod(-372, -360)* also returns -12.

NAME

fmtmsg − print formatted error messages

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <fmtmsg.h>

int fmtmsg(long classification, const char *label,
    int severity, const char *text,
    const char *action, const char *tag);
```

DESCRIPTION

This function displays a message described by its arguments on the device(s) specified in the *classification* argument. For messages written to *stderr*, the format depends on the **MSGVERB** environment variable.

The *label* argument identifies the source of the message. The string must consist of two colon separated parts where the first part has not more than 10 and the second part not more than 14 characters.

The *text* argument describes the condition of the error.

The *action* argument describes possible steps to recover from the error. If it is printed, it is prefixed by "TO FIX: ".

The *tag* argument is a reference to the online documentation where more information can be found. It should contain the *label* value and a unique identification number.

Dummy arguments

Each of the arguments can have a dummy value. The dummy classification value **MM_NULLMC** (0L) does not specify any output, so nothing is printed. The dummy severity value **NO_SEV** (0) says that no severity is supplied. The values **MM_NULLLBL**, **MM_NULLTXT**, **MM_NULLACT**, **MM_NULLTAG** are synonyms for *((char *) 0)*, the empty string, and **MM_NULLSEV** is a synonym for **NO_SEV**.

The classification argument

The *classification* argument is the sum of values describing 4 types of information.

The first value defines the output channel.

MM_PRINT Output to *stderr*.

MM_CONSOLE
: Output to the system console.

MM_PRINT | MM_CONSOLE
: Output to both.

The second value is the source of the error:

MM_HARD A hardware error occurred.

MM_FIRM A firmware error occurred.

MM_SOFT A software error occurred.

The third value encodes the detector of the problem:

MM_APPL It is detected by an application.

MM_UTIL It is detected by a utility.

MM_OPSYS
: It is detected by the operating system.

The fourth value shows the severity of the incident:

MM_RECOVER
: It is a recoverable error.

MM_NRECOV
: It is a nonrecoverable error.

The severity argument

The *severity* argument can take one of the following values:

MM_NOSEV
No severity is printed.

MM_HALT This value is printed as HALT.

MM_ERROR
This value is printed as ERROR.

MM_WARNING
This value is printed as WARNING.

MM_INFO This value is printed as INFO.

The numeric values are between 0 and 4. Using *addseverity*(3) or the environment variable **SEV_LEVEL** you can add more levels and strings to print.

RETURN VALUE

The function can return 4 values:

MM_OK Everything went smooth.

MM_NOTOK
Complete failure.

MM_NOMSG
Error writing to *stderr*.

MM_NOCON
Error writing to the console.

ENVIRONMENT

The environment variable **MSGVERB** ("message verbosity") can be used to suppress parts of the output to *stderr*. (It does not influence output to the console.) When this variable is defined, is non-NULL, and is a colon-separated list of valid keywords, then only the parts of the message corresponding to these keywords is printed. Valid keywords are "label", "severity", "text", "action", and "tag".

The environment variable **SEV_LEVEL** can be used to introduce new severity levels. By default, only the five severity levels described above are available. Any other numeric value would make **fmtmsg**() print nothing. If the user puts **SEV_LEVEL** with a format like

SEV_LEVEL=[description[:description[:...]]]

in the environment of the process before the first call to **fmtmsg**(), where each description is of the form

severity-keyword,level,printstring

then **fmtmsg**() will also accept the indicated values for the level (in addition to the standard levels 0–4), and use the indicated printstring when such a level occurs.

The severity-keyword part is not used by **fmtmsg**() but it has to be present. The level part is a string representation of a number. The numeric value must be a number greater than 4. This value must be used in the severity argument of **fmtmsg**() to select this class. It is not possible to overwrite any of the predefined classes. The printstring is the string printed when a message of this class is processed by **fmtmsg**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fmtmsg()	Thread safety	glibc >= 2.16: MT-Safe; glibc < 2.16: MT-Unsafe

Before glibc 2.16, the **fmtmsg**() function uses a static variable that is not protected, so it is not thread-safe.

Since glibc 2.16, the **fmtmsg**() function uses a lock to protect the static variable, so it is thread-safe.

STANDARDS

fmtmsg()
MSGVERB
POSIX.1-2008.

HISTORY

fmtmsg()
System V. POSIX.1-2001 and POSIX.1-2008. glibc 2.1.

MSGVERB
System V. POSIX.1-2001 and POSIX.1-2008.

SEV_LEVEL
System V.

System V and UnixWare man pages tell us that these functions have been replaced by "pfmt() and addsev()" or by "pfmt(), vpfmt(), lfmt(), and vlfmt()", and will be removed later.

EXAMPLES

```
#include <fmtmsg.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    long class = MM_PRINT | MM_SOFT | MM_OPSYS | MM_RECOVER;
    int err;

    err = fmtmsg(class, "util-linux:mount", MM_ERROR,
                 "unknown mount option", "See mount(8).",
                 "util-linux:mount:017");
    switch (err) {
    case MM_OK:
        break;
    case MM_NOTOK:
        printf("Nothing printed\n");
        break;
    case MM_NOMSG:
        printf("Nothing printed to stderr\n");
        break;
    case MM_NOCON:
        printf("No console output\n");
        break;
    default:
        printf("Unknown error from fmtmsg()\n");
    }
    exit(EXIT_SUCCESS);
}
```

The output should be:

```
util-linux:mount: ERROR: unknown mount option
TO FIX: See mount(8).  util-linux:mount:017
```

and after

```
MSGVERB=text:action; export MSGVERB
```

the output becomes:

```
unknown mount option
TO FIX: See mount(8).
```

NAME

fnmatch − match filename or pathname

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <fnmatch.h>

int fnmatch(const char ****pattern*, const char ****string***, int** *flags***);**

DESCRIPTION

The **fnmatch**() function checks whether the *string* argument matches the *pattern* argument, which is a shell wildcard pattern (see *glob*(7)).

The *flags* argument modifies the behavior; it is the bitwise OR of zero or more of the following flags:

FNM_NOESCAPE
If this flag is set, treat backslash as an ordinary character, instead of an escape character.

FNM_PATHNAME
If this flag is set, match a slash in *string* only with a slash in *pattern* and not by an asterisk (*) or a question mark (?) metacharacter, nor by a bracket expression ([]) containing a slash.

FNM_PERIOD
If this flag is set, a leading period in *string* has to be matched exactly by a period in *pattern*. A period is considered to be leading if it is the first character in *string*, or if both **FNM_PATHNAME** is set and the period immediately follows a slash.

FNM_FILE_NAME
This is a GNU synonym for **FNM_PATHNAME**.

FNM_LEADING_DIR
If this flag (a GNU extension) is set, the pattern is considered to be matched if it matches an initial segment of *string* which is followed by a slash. This flag is mainly for the internal use of glibc and is implemented only in certain cases.

FNM_CASEFOLD
If this flag (a GNU extension) is set, the pattern is matched case-insensitively.

FNM_EXTMATCH
If this flag (a GNU extension) is set, extended patterns are supported, as introduced by 'ksh' and now supported by other shells. The extended format is as follows, with *pattern−list* being a '|' separated list of patterns.

'?(*pattern−list*)'
The pattern matches if zero or one occurrences of any of the patterns in the *pattern−list* match the input *string*.

'*(*pattern−list*)'
The pattern matches if zero or more occurrences of any of the patterns in the *pattern−list* match the input *string*.

'+(*pattern−list*)'
The pattern matches if one or more occurrences of any of the patterns in the *pattern−list* match the input *string*.

'@(*pattern−list*)'
The pattern matches if exactly one occurrence of any of the patterns in the *pattern−list* match the input *string*.

'!(*pattern−list*)'
The pattern matches if the input *string* cannot be matched with any of the patterns in the *pattern−list*.

RETURN VALUE

Zero if *string* matches *pattern*, **FNM_NOMATCH** if there is no match or another nonzero value if there is an error.

NAME

fopen, fdopen, freopen − stream open functions

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

FILE *fopen(const char *restrict pathname, const char *restrict mode);
FILE *fdopen(int fd, const char *mode);
FILE *freopen(const char *restrict pathname, const char *restrict mode,
              FILE *restrict stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fdopen():
_POSIX_C_SOURCE

DESCRIPTION

The **fopen**() function opens the file whose name is the string pointed to by *pathname* and associates a stream with it.

The argument *mode* points to a string beginning with one of the following sequences (possibly followed by additional characters, as described below):

r Open text file for reading. The stream is positioned at the beginning of the file.

r+ Open for reading and writing. The stream is positioned at the beginning of the file.

w Truncate file to zero length or create text file for writing. The stream is positioned at the beginning of the file.

w+ Open for reading and writing. The file is created if it does not exist, otherwise it is truncated. The stream is positioned at the beginning of the file.

a Open for appending (writing at end of file). The file is created if it does not exist. The stream is positioned at the end of the file.

a+ Open for reading and appending (writing at end of file). The file is created if it does not exist. Output is always appended to the end of the file. POSIX is silent on what the initial read position is when using this mode. For glibc, the initial file position for reading is at the beginning of the file, but for Android/BSD/MacOS, the initial file position for reading is at the end of the file.

The *mode* string can also include the letter 'b' either as a last character or as a character between the characters in any of the two-character strings described above. This is strictly for compatibility with ISO C and has no effect; the 'b' is ignored on all POSIX conforming systems, including Linux. (Other systems may treat text files and binary files differently, and adding the 'b' may be a good idea if you do I/O to a binary file and expect that your program may be ported to non-UNIX environments.)

See NOTES below for details of glibc extensions for *mode*.

Any created file will have the mode **S_IRUSR** | **S_IWUSR** | **S_IRGRP** | **S_IWGRP** | **S_IROTH** | **S_IWOTH** (0666), as modified by the process's umask value (see *umask*(2)).

Reads and writes may be intermixed on read/write streams in any order. Note that ANSI C requires that a file positioning function intervene between output and input, unless an input operation encounters end-of-file. (If this condition is not met, then a read is allowed to return the result of writes other than the most recent.) Therefore it is good practice (and indeed sometimes necessary under Linux) to put an *fseek*(3) or *fsetpos*(3) operation between write and read operations on such a stream. This operation may be an apparent no-op (as in *fseek(..., 0L, SEEK_CUR)* called for its synchronizing side effect).

Opening a file in append mode (**a** as the first character of *mode*) causes all subsequent write operations to this stream to occur at end-of-file, as if preceded by the call:

```
fseek(stream, 0, SEEK_END);
```

The file descriptor associated with the stream is opened as if by a call to *open*(2) with the following flags:

fopen() mode	**open() flags**
r	O_RDONLY
w	O_WRONLY | O_CREAT | O_TRUNC
a	O_WRONLY | O_CREAT | O_APPEND
r+	O_RDWR
w+	O_RDWR | O_CREAT | O_TRUNC
a+	O_RDWR | O_CREAT | O_APPEND

fdopen()

The **fdopen**() function associates a stream with the existing file descriptor, *fd*. The *mode* of the stream (one of the values "r", "r+", "w", "w+", "a", "a+") must be compatible with the mode of the file descriptor. The file position indicator of the new stream is set to that belonging to *fd*, and the error and end-of-file indicators are cleared. Modes "w" or "w+" do not cause truncation of the file. The file descriptor is not dup'ed, and will be closed when the stream created by **fdopen**() is closed. The result of applying **fdopen**() to a shared memory object is undefined.

freopen()

The **freopen**() function opens the file whose name is the string pointed to by *pathname* and associates the stream pointed to by *stream* with it. The original stream (if it exists) is closed. The *mode* argument is used just as in the **fopen**() function.

If the *pathname* argument is a null pointer, **freopen**() changes the mode of the stream to that specified in *mode*; that is, **freopen**() reopens the pathname that is associated with the stream. The specification for this behavior was added in the C99 standard, which says:

> In this case, the file descriptor associated with the stream need not be closed if the call to **freopen**() succeeds. It is implementation-defined which changes of mode are permitted (if any), and under what circumstances.

The primary use of the **freopen**() function is to change the file associated with a standard text stream (*stderr*, *stdin*, or *stdout*).

RETURN VALUE

Upon successful completion **fopen**(), **fdopen**(), and **freopen**() return a *FILE* pointer. Otherwise, NULL is returned and *errno* is set to indicate the error.

ERRORS

EINVAL

The *mode* provided to **fopen**(), **fdopen**(), or **freopen**() was invalid.

The **fopen**(), **fdopen**(), and **freopen**() functions may also fail and set *errno* for any of the errors specified for the routine *malloc*(3).

The **fopen**() function may also fail and set *errno* for any of the errors specified for the routine *open*(2).

The **fdopen**() function may also fail and set *errno* for any of the errors specified for the routine *fcntl*(2).

The **freopen**() function may also fail and set *errno* for any of the errors specified for the routines *open*(2), *fclose*(3), and *fflush*(3).

NOTES

glibc notes

The GNU C library allows the following extensions for the string specified in *mode*:

c (since glibc 2.3.3)
Do not make the open operation, or subsequent read and write operations, thread cancelation points. This flag is ignored for **fdopen**().

e (since glibc 2.7)
Open the file with the **O_CLOEXEC** flag. See *open*(2) for more information. This flag is ignored for **fdopen**().

m (since glibc 2.3)
Attempt to access the file using *mmap*(2), rather than I/O system calls (**read**(2), *write*(2)). Currently, use of *mmap*(2) is attempted only for a file opened for reading.

x Open the file exclusively (like the **O_EXCL** flag of *open*(2)). If the file already exists, **fopen**() fails, and sets *errno* to **EEXIST**. This flag is ignored for **fdopen**().

In addition to the above characters, **fopen**() and **freopen**() support the following syntax in *mode*:

,ccs=*string*

The given *string* is taken as the name of a coded character set and the stream is marked as wide-oriented. Thereafter, internal conversion functions convert I/O to and from the character set *string*. If the **,ccs=***string* syntax is not specified, then the wide-orientation of the stream is determined by the first file operation. If that operation is a wide-character operation, the stream is marked wide-oriented, and functions to convert to the coded character set are loaded.

BUGS

When parsing for individual flag characters in *mode* (i.e., the characters preceding the "ccs" specification), the glibc implementation of **fopen**() and **freopen**() limits the number of characters examined in *mode* to 7 (or, before glibc 2.14, to 6, which was not enough to include possible specifications such as "rb+cmxe"). The current implementation of **fdopen**() parses at most 5 characters in *mode*.

NAME

fopencookie − open a custom stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE       /* See feature_test_macros(7) */
#define _FILE_OFFSET_BITS 64
#include <stdio.h>

FILE *fopencookie(void *restrict cookie, const char *restrict mode,
                  cookie_io_functions_t io_funcs);
```

DESCRIPTION

The **fopencookie**() function allows the programmer to create a custom implementation for a standard I/O stream. This implementation can store the stream's data at a location of its own choosing; for example, **fopencookie**() is used to implement *fmemopen*(3), which provides a stream interface to data that is stored in a buffer in memory.

In order to create a custom stream the programmer must:

- Implement four "hook" functions that are used internally by the standard I/O library when performing I/O on the stream.
- Define a "cookie" data type, a structure that provides bookkeeping information (e.g., where to store data) used by the aforementioned hook functions. The standard I/O package knows nothing about the contents of this cookie (thus it is typed as *void* * when passed to *fopencookie*()), but automatically supplies the cookie as the first argument when calling the hook functions.
- Call **fopencookie**() to open a new stream and associate the cookie and hook functions with that stream.

The **fopencookie**() function serves a purpose similar to *fopen*(3): it opens a new stream and returns a pointer to a *FILE* object that is used to operate on that stream.

The *cookie* argument is a pointer to the caller's cookie structure that is to be associated with the new stream. This pointer is supplied as the first argument when the standard I/O library invokes any of the hook functions described below.

The *mode* argument serves the same purpose as for *fopen*(3). The following modes are supported: *r*, *w*, *a*, *r+*, *w+*, and *a+*. See *fopen*(3) for details.

The *io_funcs* argument is a structure that contains four fields pointing to the programmer-defined hook functions that are used to implement this stream. The structure is defined as follows

```
typedef struct {
    cookie_read_function_t  *read;
    cookie_write_function_t *write;
    cookie_seek_function_t  *seek;
    cookie_close_function_t *close;
} cookie_io_functions_t;
```

The four fields are as follows:

*cookie_read_function_t *read*

This function implements read operations for the stream. When called, it receives three arguments:

```
ssize_t read(void *cookie, char *buf, size_t size);
```

The *buf* and *size* arguments are, respectively, a buffer into which input data can be placed and the size of that buffer. As its function result, the *read* function should return the number of bytes copied into *buf*, 0 on end of file, or −1 on error. The *read* function should update the stream offset appropriately.

If **read* is a null pointer, then reads from the custom stream always return end of file.

*cookie_write_function_t *write*
: This function implements write operations for the stream. When called, it receives three arguments:

```
ssize_t write(void *cookie, const char *buf, size_t size);
```

The *buf* and *size* arguments are, respectively, a buffer of data to be output to the stream and the size of that buffer. As its function result, the *write* function should return the number of bytes copied from *buf*, or 0 on error. (The function must not return a negative value.) The *write* function should update the stream offset appropriately.

If **write* is a null pointer, then output to the stream is discarded.

*cookie_seek_function_t *seek*
: This function implements seek operations on the stream. When called, it receives three arguments:

```
int seek(void *cookie, off_t *offset, int whence);
```

The **offset* argument specifies the new file offset depending on which of the following three values is supplied in *whence*:

SEEK_SET
: The stream offset should be set **offset* bytes from the start of the stream.

SEEK_CUR
: **offset* should be added to the current stream offset.

SEEK_END
: The stream offset should be set to the size of the stream plus **offset*.

Before returning, the *seek* function should update **offset* to indicate the new stream offset.

As its function result, the *seek* function should return 0 on success, and −1 on error.

If **seek* is a null pointer, then it is not possible to perform seek operations on the stream.

*cookie_close_function_t *close*
: This function closes the stream. The hook function can do things such as freeing buffers allocated for the stream. When called, it receives one argument:

```
int close(void *cookie);
```

The *cookie* argument is the cookie that the programmer supplied when calling **fopencookie**().

As its function result, the *close* function should return 0 on success, and **EOF** on error.

If **close* is NULL, then no special action is performed when the stream is closed.

RETURN VALUE

On success **fopencookie**() returns a pointer to the new stream. On error, NULL is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fopencookie()	Thread safety	MT-Safe

STANDARDS

GNU.

EXAMPLES

The program below implements a custom stream whose functionality is similar (but not identical) to that available via *fmemopen*(3). It implements a stream whose data is stored in a memory buffer. The program writes its command-line arguments to the stream, and then seeks through the stream reading two out of every five characters and writing them to standard output. The following shell session demonstrates the use of the program:

```
$ ./a.out 'hello world'
/he/
/ w/
/d/
Reached end of file
```

Note that a more general version of the program below could be improved to more robustly handle various error situations (e.g., opening a stream with a cookie that already has an open stream; closing a stream that has already been closed).

Program source

```
#define _GNU_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <unistd.h>

#define INIT_BUF_SIZE 4

struct memfile_cookie {
    char   *buf;        /* Dynamically sized buffer for data */
    size_t  allocated;  /* Size of buf */
    size_t  endpos;     /* Number of characters in buf */
    off_t   offset;     /* Current file offset in buf */
};

ssize_t
memfile_write(void *c, const char *buf, size_t size)
{
    char *new_buff;
    struct memfile_cookie *cookie = c;

    /* Buffer too small? Keep doubling size until big enough. */

    while (size + cookie->offset > cookie->allocated) {
        new_buff = realloc(cookie->buf, cookie->allocated * 2);
        if (new_buff == NULL)
            return -1;
        cookie->allocated *= 2;
        cookie->buf = new_buff;
    }

    memcpy(cookie->buf + cookie->offset, buf, size);

    cookie->offset += size;
    if (cookie->offset > cookie->endpos)
        cookie->endpos = cookie->offset;

    return size;
}

ssize_t
memfile_read(void *c, char *buf, size_t size)
{
    ssize_t xbytes;
    struct memfile_cookie *cookie = c;

    /* Fetch minimum of bytes requested and bytes available. */

    xbytes = size;
    if (cookie->offset + size > cookie->endpos)
        xbytes = cookie->endpos - cookie->offset;
    if (xbytes < 0)     /* offset may be past endpos */
```

```
            xbytes = 0;

        memcpy(buf, cookie->buf + cookie->offset, xbytes);

        cookie->offset += xbytes;
        return xbytes;
    }

        if (whence == SEEK_SET)
            new_offset = *offset;
        else if (whence == SEEK_END)
            new_offset = cookie->endpos + *offset;
        else if (whence == SEEK_CUR)
            new_offset = cookie->offset + *offset;
        else
            return -1;

        if (new_offset < 0)
            return -1;

        cookie->offset = new_offset;
        *offset = new_offset;
        return 0;
    }

    int
    memfile_close(void *c)
    {
        struct memfile_cookie *cookie = c;

        free(cookie->buf);
        cookie->allocated = 0;
        cookie->buf = NULL;

        return 0;
    }

    int
    main(int argc, char *argv[])
    {
        cookie_io_functions_t  memfile_func = {
            .read  = memfile_read,
            .write = memfile_write,
            .seek  = memfile_seek,
            .close = memfile_close
        };
        FILE *stream;
        struct memfile_cookie mycookie;
        size_t nread;
        char buf[1000];

        /* Set up the cookie before calling fopencookie(). */
```

```
        mycookie.buf = malloc(INIT_BUF_SIZE);
        if (mycookie.buf == NULL) {
            perror("malloc");
            exit(EXIT_FAILURE);
        }

        mycookie.allocated = INIT_BUF_SIZE;
        mycookie.offset = 0;
        mycookie.endpos = 0;

        stream = fopencookie(&mycookie, "w+", memfile_func);
        if (stream == NULL) {
            perror("fopencookie");
            exit(EXIT_FAILURE);
        }

        /* Write command-line arguments to our file. */

        for (size_t j = 1; j < argc; j++)
            if (fputs(argv[j], stream) == EOF) {
                perror("fputs");
                exit(EXIT_FAILURE);
            }

        /* Read two bytes out of every five, until EOF. */

        for (long p = 0; ; p += 5) {
            if (fseek(stream, p, SEEK_SET) == -1) {
                perror("fseek");
                exit(EXIT_FAILURE);
            }
            nread = fread(buf, 1, 2, stream);
            if (nread == 0) {
                if (ferror(stream) != 0) {
                    fprintf(stderr, "fread failed\n");
                    exit(EXIT_FAILURE);
                }
                printf("Reached end of file\n");
                break;
            }

            printf("/%.*s/\n", (int) nread, buf);
        }

        free(mycookie.buf);

        exit(EXIT_SUCCESS);
    }
```

NOTES

_FILE_OFFSET_BITS should be defined to be 64 in code that uses non-null *seek* or that takes the address of **fopencookie**, if the code is intended to be portable to traditional 32-bit x86 and ARM platforms where **off_t**'s width defaults to 32 bits.

NAME

fpathconf, pathconf − get configuration values for files

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

long fpathconf(int *fd***, int** *name***);**
long pathconf(const char * *path***, int** *name***);**

DESCRIPTION

fpathconf() gets a value for the configuration option *name* for the open file descriptor *fd*.

pathconf() gets a value for configuration option *name* for the filename *path*.

The corresponding macros defined in *<unistd.h>* are minimum values; if an application wants to take advantage of values which may change, a call to **fpathconf**() or **pathconf**() can be made, which may yield more liberal results.

Setting *name* equal to one of the following constants returns the following configuration options:

_PC_LINK_MAX
The maximum number of links to the file. If *fd* or *path* refer to a directory, then the value applies to the whole directory. The corresponding macro is **_POSIX_LINK_MAX**.

_PC_MAX_CANON
The maximum length of a formatted input line, where *fd* or *path* must refer to a terminal. The corresponding macro is **_POSIX_MAX_CANON**.

_PC_MAX_INPUT
The maximum length of an input line, where *fd* or *path* must refer to a terminal. The corresponding macro is **_POSIX_MAX_INPUT**.

_PC_NAME_MAX
The maximum length of a filename in the directory *path* or *fd* that the process is allowed to create. The corresponding macro is **_POSIX_NAME_MAX**.

_PC_PATH_MAX
The maximum length of a relative pathname when *path* or *fd* is the current working directory. The corresponding macro is **_POSIX_PATH_MAX**.

_PC_PIPE_BUF
The maximum number of bytes that can be written atomically to a pipe of FIFO. For **fpathconf**(), *fd* should refer to a pipe or FIFO. For **fpathconf**(), *path* should refer to a FIFO or a directory; in the latter case, the returned value corresponds to FIFOs created in that directory. The corresponding macro is **_POSIX_PIPE_BUF**.

_PC_CHOWN_RESTRICTED
This returns a positive value if the use of *chown*(2) and *fchown*(2) for changing a file's user ID is restricted to a process with appropriate privileges, and changing a file's group ID to a value other than the process's effective group ID or one of its supplementary group IDs is restricted to a process with appropriate privileges. According to POSIX.1, this variable shall always be defined with a value other than −1. The corresponding macro is **_POSIX_CHOWN_RESTRICTED**.

If *fd* or *path* refers to a directory, then the return value applies to all files in that directory.

_PC_NO_TRUNC
This returns nonzero if accessing filenames longer than **_POSIX_NAME_MAX** generates an error. The corresponding macro is **_POSIX_NO_TRUNC**.

_PC_VDISABLE
This returns nonzero if special character processing can be disabled, where *fd* or *path* must refer to a terminal.

RETURN VALUE

The return value of these functions is one of the following:

- On error, −1 is returned and *errno* is set to indicate the error (for example, **EINVAL**, indicating that *name* is invalid).
- If *name* corresponds to a maximum or minimum limit, and that limit is indeterminate, −1 is returned and *errno* is not changed. (To distinguish an indeterminate limit from an error, set *errno* to zero before the call, and then check whether *errno* is nonzero when −1 is returned.)
- If *name* corresponds to an option, a positive value is returned if the option is supported, and −1 is returned if the option is not supported.
- Otherwise, the current value of the option or limit is returned. This value will not be more restrictive than the corresponding value that was described to the application in <*unistd.h*> or <*limits.h*> when the application was compiled.

ERRORS

EACCES
(**pathconf**()) Search permission is denied for one of the directories in the path prefix of *path*.

EBADF
(**fpathconf**()) *fd* is not a valid file descriptor.

EINVAL
name is invalid.

EINVAL
The implementation does not support an association of *name* with the specified file.

ELOOP
(**pathconf**()) Too many symbolic links were encountered while resolving *path*.

ENAMETOOLONG
(**pathconf**()) *path* is too long.

ENOENT
(**pathconf**()) A component of *path* does not exist, or *path* is an empty string.

ENOTDIR
(**pathconf**()) A component used as a directory in *path* is not in fact a directory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fpathconf(), **pathconf**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

Files with name lengths longer than the value returned for *name* equal to **_PC_NAME_MAX** may exist in the given directory.

Some returned values may be huge; they are not suitable for allocating memory.

NAME

fpclassify, isfinite, isnormal, isnan, isinf − floating-point classification macros

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

int fpclassify(x);
int isfinite(x);
int isnormal(x);
int isnan(x);
int isinf(x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fpclassify(), **isfinite**(), **isnormal**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

isnan():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

isinf():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

Floating point numbers can have special values, such as infinite or NaN. With the macro **fpclassify(***x***)** you can find out what type *x* is. The macro takes any floating-point expression as argument. The result is one of the following values:

FP_NAN *x* is "Not a Number".

FP_INFINITE *x* is either positive infinity or negative infinity.

FP_ZERO *x* is zero.

FP_SUBNORMAL
x is too small to be represented in normalized format.

FP_NORMAL if nothing of the above is correct then it must be a normal floating-point number.

The other macros provide a short answer to some standard questions.

isfinite(*x***)** returns a nonzero value if
(fpclassify(x) != FP_NAN && fpclassify(x) != FP_INFINITE)

isnormal(*x***)** returns a nonzero value if (fpclassify(x) == FP_NORMAL)

isnan(*x***)** returns a nonzero value if (fpclassify(x) == FP_NAN)

isinf(*x***)** returns 1 if *x* is positive infinity, and −1 if *x* is negative infinity.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fpclassify(), **isfinite**(), **isnormal**(), **isnan**(), **isinf**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

In glibc 2.01 and earlier, **isinf**() returns a nonzero value (actually: 1) if *x* is positive infinity or negative infinity. (This is all that C99 requires.)

NOTES

For **isinf**(), the standards merely say that the return value is nonzero if and only if the argument has an infinite value.

SEE ALSO

finite(3), *INFINITY*(3), *isgreater*(3), *signbit*(3)

NAME

fpurge, __fpurge − purge a stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
/* unsupported */
#include <stdio.h>

int fpurge(FILE *stream);

/* supported */
#include <stdio.h>
#include <stdio_ext.h>

void  __fpurge(FILE *stream);
```

DESCRIPTION

The function **fpurge**() clears the buffers of the given stream. For output streams this discards any unwritten output. For input streams this discards any input read from the underlying object but not yet obtained via *getc*(3); this includes any text pushed back via *ungetc*(3). See also *fflush*(3).

The function **__fpurge**() does precisely the same, but without returning a value.

RETURN VALUE

Upon successful completion **fpurge**() returns 0. On error, it returns −1 and sets *errno* to indicate the error.

ERRORS

EBADF
: *stream* is not an open stream.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
__fpurge()	Thread safety	MT-Safe race:stream

STANDARDS

None.

HISTORY

fpurge()
: 4.4BSD. Not available under Linux.

__fpurge()
: Solaris, glibc 2.1.95.

NOTES

Usually it is a mistake to want to discard input buffers.

SEE ALSO

fflush(3), *setbuf*(3), *stdio_ext*(3)

NAME

fputwc, putwc − write a wide character to a FILE stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);
wint_t putwc(wchar_t wc, FILE *stream);
```

DESCRIPTION

The **fputwc**() function is the wide-character equivalent of the *fputc*(3) function. It writes the wide character *wc* to *stream*. If *ferror(stream)* becomes true, it returns **WEOF**. If a wide-character conversion error occurs, it sets *errno* to **EILSEQ** and returns **WEOF**. Otherwise, it returns *wc*.

The **putwc**() function or macro functions identically to **fputwc**(). It may be implemented as a macro, and may evaluate its argument more than once. There is no reason ever to use it.

For nonlocking counterparts, see *unlocked_stdio*(3).

RETURN VALUE

On success, **fputwc**() function returns *wc*. Otherwise, **WEOF** is returned, and *errno* is set to indicate the error.

ERRORS

Apart from the usual ones, there is

EILSEQ
: Conversion of *wc* to the stream's encoding fails.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fputwc(), **putwc**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

NOTES

The behavior of **fputwc**() depends on the **LC_CTYPE** category of the current locale.

In the absence of additional information passed to the *fopen*(3) call, it is reasonable to expect that **fputwc**() will actually write the multibyte sequence corresponding to the wide character *wc*.

SEE ALSO

fgetwc(3), *fputws*(3), *unlocked_stdio*(3)

NAME

fputws − write a wide-character string to a FILE stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

int fputws(const wchar_t *restrict *ws***, FILE *restrict** *stream***);**

DESCRIPTION

The **fputws**() function is the wide-character equivalent of the *fputs*(3) function. It writes the wide-character string starting at *ws*, up to but not including the terminating null wide character (L'\0'), to *stream*.

For a nonlocking counterpart, see *unlocked_stdio*(3).

RETURN VALUE

The **fputws**() function returns a nonnegative integer if the operation was successful, or −1 to indicate an error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fputws()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **fputws**() depends on the **LC_CTYPE** category of the current locale.

In the absence of additional information passed to the *fopen*(3) call, it is reasonable to expect that **fputws**() will actually write the multibyte string corresponding to the wide-character string *ws*.

SEE ALSO

fputwc(3), *unlocked_stdio*(3)

NAME

fread, fwrite − binary stream input/output

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

size_t fread(void ptr[restrict .size * .nmemb],
             size_t size, size_t nmemb,
             FILE *restrict stream);
size_t fwrite(const void ptr[restrict .size * .nmemb],
              size_t size, size_t nmemb,
              FILE *restrict stream);
```

DESCRIPTION

The function **fread**() reads *nmemb* items of data, each *size* bytes long, from the stream pointed to by *stream*, storing them at the location given by *ptr*.

The function **fwrite**() writes *nmemb* items of data, each *size* bytes long, to the stream pointed to by *stream*, obtaining them from the location given by *ptr*.

For nonlocking counterparts, see *unlocked_stdio*(3).

RETURN VALUE

On success, **fread**() and **fwrite**() return the number of items read or written. This number equals the number of bytes transferred only when *size* is 1. If an error occurs, or the end of the file is reached, the return value is a short item count (or zero).

The file position indicator for the stream is advanced by the number of bytes successfully read or written.

fread() does not distinguish between end-of-file and error, and callers must use *feof*(3) and *ferror*(3) to determine which occurred.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fread(), **fwrite**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89.

EXAMPLES

The program below demonstrates the use of **fread**() by parsing /bin/sh ELF executable in binary mode and printing its magic and class:

```
$ ./a.out
ELF magic: 0x7f454c46
Class: 0x02
```

Program source

```
#include <stdio.h>
#include <stdlib.h>

#define ARRAY_SIZE(arr) (sizeof(arr) / sizeof((arr)[0]))

int
main(void)
{
    FILE           *fp;
    size_t         ret;
```

```
        unsigned char  buffer[4];

        fp = fopen("/bin/sh", "rb");
        if (!fp) {
            perror("fopen");
            return EXIT_FAILURE;
        }

        ret = fread(buffer, sizeof(*buffer), ARRAY_SIZE(buffer), fp);
        if (ret != ARRAY_SIZE(buffer)) {
            fprintf(stderr, "fread() failed: %zu\n", ret);
            exit(EXIT_FAILURE);
        }

        printf("ELF magic: %#04x%02x%02x%02x\n", buffer[0], buffer[1],
               buffer[2], buffer[3]);

        ret = fread(buffer, 1, 1, fp);
        if (ret != 1) {
            fprintf(stderr, "fread() failed: %zu\n", ret);
            exit(EXIT_FAILURE);
        }

        printf("Class: %#04x\n", buffer[0]);

        fclose(fp);

        exit(EXIT_SUCCESS);
    }
```

NAME

frexp, frexpf, frexpl − convert floating-point number to fractional and integral components

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double frexp(double x, int *exp);
float frexpf(float x, int *exp);
long double frexpl(long double x, int *exp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

frexpf(), **frexpl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions are used to split the number *x* into a normalized fraction and an exponent which is stored in *exp*.

RETURN VALUE

These functions return the normalized fraction. If the argument *x* is not zero, the normalized fraction is *x* times a power of two, and its absolute value is always in the range 1/2 (inclusive) to 1 (exclusive), that is, [0.5,1).

If *x* is zero, then the normalized fraction is zero and zero is stored in *exp*.

If *x* is a NaN, a NaN is returned, and the value of **exp* is unspecified.

If *x* is positive infinity (negative infinity), positive infinity (negative infinity) is returned, and the value of **exp* is unspecified.

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
frexp(), **frexpf**(), **frexpl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

EXAMPLES

The program below produces results such as the following:

```
$ ./a.out 2560
frexp(2560, &e) = 0.625: 0.625 * 2^12 = 2560
$ ./a.out -4
frexp(-4, &e) = -0.5: -0.5 * 2^3 = -4
```

Program source

```
#include <float.h>
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
```

```
    {
        double x, r;
        int exp;

        x = strtod(argv[1], NULL);
        r = frexp(x, &exp);

        printf("frexp(%g, &e) = %g: %g * %d^%d = %g\n", x, r, r, 2, exp, x);
        exit(EXIT_SUCCESS);
    }
```

SEE ALSO

ldexp(3), *modf*(3)

NAME

fgetpos, fseek, fsetpos, ftell, rewind − reposition a stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int fseek(FILE *stream, long offset, int whence);
long ftell(FILE *stream);

void rewind(FILE *stream);

int fgetpos(FILE *restrict stream, fpos_t *restrict pos);
int fsetpos(FILE *stream, const fpos_t *pos);
```

DESCRIPTION

The **fseek**() function sets the file position indicator for the stream pointed to by *stream*. The new position, measured in bytes, is obtained by adding *offset* bytes to the position specified by *whence*. If *whence* is set to **SEEK_SET**, **SEEK_CUR**, or **SEEK_END**, the offset is relative to the start of the file, the current position indicator, or end-of-file, respectively. A successful call to the **fseek**() function clears the end-of-file indicator for the stream and undoes any effects of the *ungetc*(3) function on the same stream.

The **ftell**() function obtains the current value of the file position indicator for the stream pointed to by *stream*.

The **rewind**() function sets the file position indicator for the stream pointed to by *stream* to the beginning of the file. It is equivalent to:

```
(void) fseek(stream, 0L, SEEK_SET)
```

except that the error indicator for the stream is also cleared (see *clearerr*(3)).

The **fgetpos**() and **fsetpos**() functions are alternate interfaces equivalent to **ftell**() and **fseek**() (with *whence* set to **SEEK_SET**), setting and storing the current value of the file offset into or from the object referenced by *pos*. On some non-UNIX systems, an *fpos_t* object may be a complex object and these routines may be the only way to portably reposition a text stream.

If the stream refers to a regular file and the resulting stream offset is beyond the size of the file, subsequent writes will extend the file with a hole, up to the offset, before committing any data. See *lseek*(2) for details on file seeking semantics.

RETURN VALUE

The **rewind**() function returns no value. Upon successful completion, **fgetpos**(), **fseek**(), **fsetpos**() return 0, and **ftell**() returns the current offset. Otherwise, −1 is returned and *errno* is set to indicate the error.

ERRORS

EINVAL
: The *whence* argument to **fseek**() was not **SEEK_SET**, **SEEK_END**, or **SEEK_CUR**. Or: the resulting file offset would be negative.

ESPIPE
: The file descriptor underlying *stream* is not seekable (e.g., it refers to a pipe, FIFO, or socket).

The functions **fgetpos**(), **fseek**(), **fsetpos**(), and **ftell**() may also fail and set *errno* for any of the errors specified for the routines *fflush*(3), *fstat*(2), *lseek*(2), and *malloc*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

fseeko, ftello − seek to or report file position

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int fseeko(FILE *stream, off_t offset, int whence);
off_t ftello(FILE *stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fseeko(), **ftello**():
_FILE_OFFSET_BITS == 64 || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **fseeko**() and **ftello**() functions are identical to *fseek*(3) and *ftell*(3) (see *fseek*(3)), respectively, except that the *offset* argument of **fseeko**() and the return value of **ftello**() is of type *off_t* instead of *long*.

On some architectures, both *off_t* and *long* are 32-bit types, but defining **_FILE_OFFSET_BITS** with the value 64 (before including *any* header files) will turn *off_t* into a 64-bit type.

RETURN VALUE

On successful completion, **fseeko**() returns 0, while **ftello**() returns the current offset. Otherwise, −1 is returned and *errno* is set to indicate the error.

ERRORS

See the ERRORS in *fseek*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fseeko(), **ftello**()	Thread safety	MT-Safe

STANDARDS

HISTORY

glibc 2.1. POSIX.1-2001, SUSv2.

NOTES

The declarations of these functions can also be obtained by defining the obsolete **_LARGEFILE_SOURCE** feature test macro.

SEE ALSO

fseek(3)

NAME

ftime − return date and time

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/timeb.h>

int ftime(struct timeb **tp*);

DESCRIPTION

NOTE: This function is no longer provided by the GNU C library. Use *clock_gettime*(2) instead.

This function returns the current time as seconds and milliseconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC). The time is returned in *tp*, which is declared as follows:

```
struct timeb {
    time_t          time;
    unsigned short millitm;
    short           timezone;
    short           dstflag;
};
```

Here *time* is the number of seconds since the Epoch, and *millitm* is the number of milliseconds since *time* seconds since the Epoch. The *timezone* field is the local timezone measured in minutes of time west of Greenwich (with a negative value indicating minutes east of Greenwich). The *dstflag* field is a flag that, if nonzero, indicates that Daylight Saving time applies locally during the appropriate part of the year.

POSIX.1-2001 says that the contents of the *timezone* and *dstflag* fields are unspecified; avoid relying on them.

RETURN VALUE

This function always returns 0. (POSIX.1-2001 specifies, and some systems document, a −1 error return.)

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ftime()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

Removed in glibc 2.33. 4.2BSD, POSIX.1-2001. Removed in POSIX.1-2008.

This function is obsolete. Don’t use it. If the time in seconds suffices, *time*(2) can be used; *gettimeofday*(2) gives microseconds; *clock_gettime*(2) gives nanoseconds but is not as widely available.

BUGS

Early glibc2 is buggy and returns 0 in the *millitm* field; glibc 2.1.1 is correct again.

SEE ALSO

gettimeofday(2), *time*(2)

NAME

ftok − convert a pathname and a project identifier to a System V IPC key

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/ipc.h>

key_t ftok(const char ****pathname*, int** *proj_id***);**

DESCRIPTION

The **ftok**() function uses the identity of the file named by the given *pathname* (which must refer to an existing, accessible file) and the least significant 8 bits of *proj_id* (which must be nonzero) to generate a *key_t* type System V IPC key, suitable for use with *msgget*(2), *semget*(2), or *shmget*(2).

The resulting value is the same for all pathnames that name the same file, when the same value of *proj_id* is used. The value returned should be different when the (simultaneously existing) files or the project IDs differ.

RETURN VALUE

On success, the generated *key_t* value is returned. On failure −1 is returned, with *errno* indicating the error as for the *stat*(2) system call.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ftok()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

On some ancient systems, the prototype was:

```
key_t ftok(char *pathname, char proj_id);
```

Today, *proj_id* is an *int*, but still only 8 bits are used. Typical usage has an ASCII character *proj_id*, that is why the behavior is said to be undefined when *proj_id* is zero.

Of course, no guarantee can be given that the resulting *key_t* is unique. Typically, a best-effort attempt combines the given *proj_id* byte, the lower 16 bits of the inode number, and the lower 8 bits of the device number into a 32-bit result. Collisions may easily happen, for example between files on */dev/hda1* and files on */dev/sda1*.

EXAMPLES

See *semget*(2).

SEE ALSO

msgget(2), *semget*(2), *shmget*(2), *stat*(2), *sysvipc*(7)

NAME

fts, fts_open, fts_read, fts_children, fts_set, fts_close − traverse a file hierarchy

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/types.h>
#include <sys/stat.h>
#include <fts.h>

FTS *fts_open(char *const * *path_argv***, int** *options***,**
int (*_Nullable *compar***)(const FTSENT **, const FTSENT **));**

FTSENT *fts_read(FTS * *ftsp***);**

FTSENT *fts_children(FTS * *ftsp***, int** *instr***);**

int fts_set(FTS * *ftsp***, FTSENT *** *f* **, int** *instr***);**

int fts_close(FTS * *ftsp***);**

DESCRIPTION

The fts functions are provided for traversing file hierarchies. A simple overview is that the **fts_open**() function returns a "handle" (of type *FTS **) that refers to a file hierarchy "stream". This handle is then supplied to the other fts functions. The function **fts_read**() returns a pointer to a structure describing one of the files in the file hierarchy. The function **fts_children**() returns a pointer to a linked list of structures, each of which describes one of the files contained in a directory in the hierarchy.

In general, directories are visited two distinguishable times; in preorder (before any of their descendants are visited) and in postorder (after all of their descendants have been visited). Files are visited once. It is possible to walk the hierarchy "logically" (visiting the files that symbolic links point to) or physically (visiting the symbolic links themselves), order the walk of the hierarchy or prune and/or revisit portions of the hierarchy.

Two structures (and associated types) are defined in the include file <*fts.h*>. The first type is *FTS*, the structure that represents the file hierarchy itself. The second type is *FTSENT*, the structure that represents a file in the file hierarchy. Normally, an *FTSENT* structure is returned for every file in the file hierarchy. In this manual page, "file" and "FTSENT structure" are generally interchangeable.

The *FTSENT* structure contains fields describing a file. The structure contains at least the following fields (there are additional fields that should be considered private to the implementation):

```
typedef struct _ftsent {
    unsigned short  fts_info;     /* flags for FTSENT structure */
    char           *fts_accpath;  /* access path */
    char           *fts_path;     /* root path */
    short           fts_pathlen;  /* strlen(fts_path) +
                                     strlen(fts_name) */
    char           *fts_name;     /* filename */
    short           fts_namelen;  /* strlen(fts_name) */
    short           fts_level;    /* depth (-1 to N) */
    int             fts_errno;    /* file errno */
    long            fts_number;   /* local numeric value */
    void           *fts_pointer;  /* local address value */
    struct _ftsent *fts_parent;   /* parent directory */
    struct _ftsent *fts_link;     /* next file structure */
    struct _ftsent *fts_cycle;    /* cycle structure */
    struct stat    *fts_statp;    /* [l]stat(2) information */
} FTSENT;
```

These fields are defined as follows:

fts_info

One of the following values describing the returned *FTSENT* structure and the file it represents. With the exception of directories without errors (**FTS_D**), all of these entries are terminal, that is, they will not be revisited, nor will any of their descendants be visited.

FTS_D A directory being visited in preorder.

FTS_DC
A directory that causes a cycle in the tree. (The *fts_cycle* field of the *FTSENT* structure will be filled in as well.)

FTS_DEFAULT
Any *FTSENT* structure that represents a file type not explicitly described by one of the other *fts_info* values.

FTS_DNR
A directory which cannot be read. This is an error return, and the *fts_errno* field will be set to indicate what caused the error.

FTS_DOT
A file named "." or ".." which was not specified as a filename to **fts_open**() (see **FTS_SEEDOT**).

FTS_DP
A directory being visited in postorder. The contents of the *FTSENT* structure will be unchanged from when it was returned in preorder, that is, with the *fts_info* field set to **FTS_D**.

FTS_ERR
This is an error return, and the *fts_errno* field will be set to indicate what caused the error.

FTS_F A regular file.

FTS_NS
A file for which no [**l**]*stat*(2) information was available. The contents of the *fts_statp* field are undefined. This is an error return, and the *fts_errno* field will be set to indicate what caused the error.

FTS_NSOK
A file for which no [**l**]*stat*(2) information was requested. The contents of the *fts_statp* field are undefined.

FTS_SL
A symbolic link.

FTS_SLNONE
A symbolic link with a nonexistent target. The contents of the *fts_statp* field reference the file characteristic information for the symbolic link itself.

fts_accpath
A path for accessing the file from the current directory.

fts_path
The path for the file relative to the root of the traversal. This path contains the path specified to **fts_open**() as a prefix.

fts_pathlen
The sum of the lengths of the strings referenced by *fts_path* and *fts_name*.

fts_name
The name of the file.

fts_namelen
The length of the string referenced by *fts_name*.

fts_level
The depth of the traversal, numbered from −1 to N, where this file was found. The *FTSENT* structure representing the parent of the starting point (or root) of the traversal is numbered −1, and the *FTSENT* structure for the root itself is numbered 0.

fts_errno
If **fts_children**() or **fts_read**() returns an *FTSENT* structure whose *fts_info* field is set to **FTS_DNR**, **FTS_ERR**, or **FTS_NS**, the *fts_errno* field contains the error number (i.e., the

errno value) specifying the cause of the error. Otherwise, the contents of the *fts_errno* field are undefined.

fts_number
This field is provided for the use of the application program and is not modified by the fts functions. It is initialized to 0.

fts_pointer
This field is provided for the use of the application program and is not modified by the fts functions. It is initialized to NULL.

fts_parent
A pointer to the *FTSENT* structure referencing the file in the hierarchy immediately above the current file, that is, the directory of which this file is a member. A parent structure for the initial entry point is provided as well, however, only the *fts_level*, *fts_number*, and *fts_pointer* fields are guaranteed to be initialized.

fts_link
Upon return from the **fts_children**() function, the *fts_link* field points to the next structure in the NULL-terminated linked list of directory members. Otherwise, the contents of the *fts_link* field are undefined.

fts_cycle
If a directory causes a cycle in the hierarchy (see **FTS_DC**), either because of a hard link between two directories, or a symbolic link pointing to a directory, the *fts_cycle* field of the structure will point to the *FTSENT* structure in the hierarchy that references the same file as the current *FTSENT* structure. Otherwise, the contents of the *fts_cycle* field are undefined.

fts_statp
A pointer to [**l**]*stat*(2) information for the file.

A single buffer is used for all of the paths of all of the files in the file hierarchy. Therefore, the *fts_path* and *fts_accpath* fields are guaranteed to be null-terminated *only* for the file most recently returned by **fts_read**(). To use these fields to reference any files represented by other *FTSENT* structures will require that the path buffer be modified using the information contained in that *FTSENT* structure's *fts_pathlen* field. Any such modifications should be undone before further calls to **fts_read**() are attempted. The *fts_name* field is always null-terminated.

fts_open()
The **fts_open**() function takes a pointer to an array of character pointers naming one or more paths which make up a logical file hierarchy to be traversed. The array must be terminated by a null pointer.

There are a number of options, at least one of which (either **FTS_LOGICAL** or **FTS_PHYSICAL**) must be specified. The options are selected by ORing the following values:

FTS_LOGICAL
This option causes the fts routines to return *FTSENT* structures for the targets of symbolic links instead of the symbolic links themselves. If this option is set, the only symbolic links for which *FTSENT* structures are returned to the application are those referencing nonexistent files: the *fts_statp* field is obtained via *stat*(2) with a fallback to *lstat*(2).

FTS_PHYSICAL
This option causes the fts routines to return *FTSENT* structures for symbolic links themselves instead of the target files they point to. If this option is set, *FTSENT* structures for all symbolic links in the hierarchy are returned to the application: the *fts_statp* field is obtained via *lstat*(2).

FTS_COMFOLLOW
This option causes any symbolic link specified as a root path to be followed immediately, as if via **FTS_LOGICAL**, regardless of the primary mode.

FTS_NOCHDIR
As a performance optimization, the fts functions change directories as they walk the file hierarchy. This has the side-effect that an application cannot rely on being in any particular directory during the traversal. This option turns off this optimization, and the fts functions will not change the current directory. Note that applications should not themselves change their

current directory and try to access files unless **FTS_NOCHDIR** is specified and absolute pathnames were provided as arguments to **fts_open**().

FTS_NOSTAT
By default, returned *FTSENT* structures reference file characteristic information (the *fts_statp* field) for each file visited. This option relaxes that requirement as a performance optimization, allowing the fts functions to set the *fts_info* field to **FTS_NSOK** and leave the contents of the *fts_statp* field undefined.

FTS_SEEDOT
By default, unless they are specified as path arguments to **fts_open**(), any files named "." or ".." encountered in the file hierarchy are ignored. This option causes the fts routines to return *FTSENT* structures for them.

FTS_XDEV
This option prevents fts from descending into directories that have a different device number than the file from which the descent began.

The argument **compar**() specifies a user-defined function which may be used to order the traversal of the hierarchy. It takes two pointers to pointers to *FTSENT* structures as arguments and should return a negative value, zero, or a positive value to indicate if the file referenced by its first argument comes before, in any order with respect to, or after, the file referenced by its second argument. The *fts_accpath*, *fts_path*, and *fts_pathlen* fields of the *FTSENT* structures may *never* be used in this comparison. If the *fts_info* field is set to **FTS_NS** or **FTS_NSOK**, the *fts_statp* field may not either. If the **compar**() argument is NULL, the directory traversal order is in the order listed in *path_argv* for the root paths, and in the order listed in the directory for everything else.

fts_read()
The **fts_read**() function returns a pointer to an *FTSENT* structure describing a file in the hierarchy. Directories (that are readable and do not cause cycles) are visited at least twice, once in preorder and once in postorder. All other files are visited at least once. (Hard links between directories that do not cause cycles or symbolic links to symbolic links may cause files to be visited more than once, or directories more than twice.)

If all the members of the hierarchy have been returned, **fts_read**() returns NULL and sets *errno* to 0. If an error unrelated to a file in the hierarchy occurs, **fts_read**() returns NULL and sets *errno* to indicate the error. If an error related to a returned file occurs, a pointer to an *FTSENT* structure is returned, and *errno* may or may not have been set (see *fts_info*).

The *FTSENT* structures returned by **fts_read**() may be overwritten after a call to **fts_close**() on the same file hierarchy stream, or, after a call to **fts_read**() on the same file hierarchy stream unless they represent a file of type directory, in which case they will not be overwritten until after a call to **fts_read**() after the *FTSENT* structure has been returned by the function **fts_read**() in postorder.

fts_children()
The **fts_children**() function returns a pointer to an *FTSENT* structure describing the first entry in a NULL-terminated linked list of the files in the directory represented by the *FTSENT* structure most recently returned by **fts_read**(). The list is linked through the *fts_link* field of the *FTSENT* structure, and is ordered by the user-specified comparison function, if any. Repeated calls to **fts_children**() will re-create this linked list.

As a special case, if **fts_read**() has not yet been called for a hierarchy, **fts_children**() will return a pointer to the files in the logical directory specified to **fts_open**(), that is, the arguments specified to **fts_open**(). Otherwise, if the *FTSENT* structure most recently returned by **fts_read**() is not a directory being visited in preorder, or the directory does not contain any files, **fts_children**() returns NULL and sets *errno* to zero. If an error occurs, **fts_children**() returns NULL and sets *errno* to indicate the error.

The *FTSENT* structures returned by **fts_children**() may be overwritten after a call to **fts_children**(), **fts_close**(), or **fts_read**() on the same file hierarchy stream.

The *instr* argument is either zero or the following value:

FTS_NAMEONLY
Only the names of the files are needed. The contents of all the fields in the returned linked list of structures are undefined with the exception of the *fts_name* and *fts_namelen* fields.

fts_set()
The function **fts_set**() allows the user application to determine further processing for the file *f* of the stream *ftsp*. The **fts_set**() function returns 0 on success, and −1 if an error occurs.

The *instr* argument is either 0 (meaning "do nothing") or one of the following values:

FTS_AGAIN
Revisit the file; any file type may be revisited. The next call to **fts_read**() will return the referenced file. The *fts_stat* and *fts_info* fields of the structure will be reinitialized at that time, but no other fields will have been changed. This option is meaningful only for the most recently returned file from **fts_read**(). Normal use is for postorder directory visits, where it causes the directory to be revisited (in both preorder and postorder) as well as all of its descendants.

FTS_FOLLOW
The referenced file must be a symbolic link. If the referenced file is the one most recently returned by **fts_read**(), the next call to **fts_read**() returns the file with the *fts_info* and *fts_statp* fields reinitialized to reflect the target of the symbolic link instead of the symbolic link itself. If the file is one of those most recently returned by **fts_children**(), the *fts_info* and *fts_statp* fields of the structure, when returned by **fts_read**(), will reflect the target of the symbolic link instead of the symbolic link itself. In either case, if the target of the symbolic link does not exist, the fields of the returned structure will be unchanged and the *fts_info* field will be set to **FTS_SLNONE**.

If the target of the link is a directory, the preorder return, followed by the return of all of its descendants, followed by a postorder return, is done.

FTS_SKIP
No descendants of this file are visited. The file may be one of those most recently returned by either **fts_children**() or **fts_read**().

fts_close()
The **fts_close**() function closes the file hierarchy stream referred to by *ftsp* and restores the current directory to the directory from which **fts_open**() was called to open *ftsp*. The **fts_close**() function returns 0 on success, and −1 if an error occurs.

ERRORS
The function **fts_open**() may fail and set *errno* for any of the errors specified for *open*(2) and *malloc*(3).

In addition, **fts_open**() may fail and set *errno* as follows:

ENOENT
Any element of *path_argv* was an empty string.

The function **fts_close**() may fail and set *errno* for any of the errors specified for *chdir*(2) and *close*(2).

The functions **fts_read**() and **fts_children**() may fail and set *errno* for any of the errors specified for *chdir*(2), *malloc*(3), *opendir*(3), *readdir*(3), and [**l**]*stat*(2).

In addition, **fts_children**(), **fts_open**(), and **fts_set**() may fail and set *errno* as follows:

EINVAL
options or *instr* was invalid.

NAME

ftw, nftw − file tree walk

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <ftw.h>

int nftw(const char *dirpath,
    int (* fn)(const char * fpath, const struct stat *sb,
        int typeflag, struct FTW * ftwbuf ),
    int nopenfd, int  flags);

[[deprecated]]
int ftw(const char *dirpath,
    int (* fn)(const char * fpath, const struct stat *sb,
        int typeflag),
    int nopenfd);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

nftw():
_XOPEN_SOURCE >= 500

DESCRIPTION

nftw() walks through the directory tree that is located under the directory *dirpath*, and calls *fn*() once for each entry in the tree. By default, directories are handled before the files and subdirectories they contain (preorder traversal).

To avoid using up all of the calling process's file descriptors, *nopenfd* specifies the maximum number of directories that **nftw**() will hold open simultaneously. When the search depth exceeds this, **nftw**() will become slower because directories have to be closed and reopened. **nftw**() uses at most one file descriptor for each level in the directory tree.

For each entry found in the tree, **nftw**() calls *fn*() with four arguments: *fpath*, *sb*, *typeflag*, and *ftwbuf*. *fpath* is the pathname of the entry, and is expressed either as a pathname relative to the calling process's current working directory at the time of the call to **nftw**(), if *dirpath* was expressed as a relative pathname, or as an absolute pathname, if *dirpath* was expressed as an absolute pathname. *sb* is a pointer to the *stat* structure returned by a call to *stat*(2) for *fpath*.

The *typeflag* argument passed to *fn*() is an integer that has one of the following values:

FTW_F
: *fpath* is a regular file.

FTW_D
: *fpath* is a directory.

FTW_DNR
: *fpath* is a directory which can't be read.

FTW_DP
: *fpath* is a directory, and **FTW_DEPTH** was specified in *flags*. (If **FTW_DEPTH** was not specified in *flags*, then directories will always be visited with *typeflag* set to **FTW_D**.) All of the files and subdirectories within *fpath* have been processed.

FTW_NS
: The *stat*(2) call failed on *fpath*, which is not a symbolic link. The probable cause for this is that the caller had read permission on the parent directory, so that the filename *fpath* could be seen, but did not have execute permission, so that the file could not be reached for *stat*(2). The contents of the buffer pointed to by *sb* are undefined.

FTW_SL
: *fpath* is a symbolic link, and **FTW_PHYS** was set in *flags*.

FTW_SLN
: *fpath* is a symbolic link pointing to a nonexistent file. (This occurs only if **FTW_PHYS** is not set.) In this case the *sb* argument passed to *fn*() contains information returned by

performing *lstat*(2) on the "dangling" symbolic link. (But see BUGS.)

The fourth argument (*ftwbuf*) that **nftw**() supplies when calling *fn*() is a pointer to a structure of type *FTW*:

```
struct FTW {
    int base;
    int level;
};
```

base is the offset of the filename (i.e., basename component) in the pathname given in *fpath*. *level* is the depth of *fpath* in the directory tree, relative to the root of the tree (*dirpath*, which has depth 0).

To stop the tree walk, *fn*() returns a nonzero value; this value will become the return value of **nftw**(). As long as *fn*() returns 0, **nftw**() will continue either until it has traversed the entire tree, in which case it will return zero, or until it encounters an error (such as a *malloc*(3) failure), in which case it will return −1.

Because **nftw**() uses dynamic data structures, the only safe way to exit out of a tree walk is to return a nonzero value from *fn*(). To allow a signal to terminate the walk without causing a memory leak, have the handler set a global flag that is checked by *fn*(). *Don't* use *longjmp*(3) unless the program is going to terminate.

The *flags* argument of **nftw**() is formed by ORing zero or more of the following flags:

FTW_ACTIONRETVAL (since glibc 2.3.3)
: If this glibc-specific flag is set, then **nftw**() handles the return value from *fn*() differently. *fn*() should return one of the following values:

  FTW_CONTINUE
  : Instructs **nftw**() to continue normally.

  FTW_SKIP_SIBLINGS
  : If *fn*() returns this value, then siblings of the current entry will be skipped, and processing continues in the parent.

  FTW_SKIP_SUBTREE
  : If *fn*() is called with an entry that is a directory (*typeflag* is **FTW_D**), this return value will prevent objects within that directory from being passed as arguments to *fn*(). **nftw**() continues processing with the next sibling of the directory.

  FTW_STOP
  : Causes **nftw**() to return immediately with the return value **FTW_STOP**.

  Other return values could be associated with new actions in the future; *fn*() should not return values other than those listed above.

  The feature test macro **_GNU_SOURCE** must be defined (before including *any* header files) in order to obtain the definition of **FTW_ACTIONRETVAL** from <*ftw.h*>.

FTW_CHDIR
: If set, do a *chdir*(2) to each directory before handling its contents. This is useful if the program needs to perform some action in the directory in which *fpath* resides. (Specifying this flag has no effect on the pathname that is passed in the *fpath* argument of *fn*.)

FTW_DEPTH
: If set, do a post-order traversal, that is, call *fn*() for the directory itself *after* handling the contents of the directory and its subdirectories. (By default, each directory is handled *before* its contents.)

FTW_MOUNT
: If set, stay within the same filesystem (i.e., do not cross mount points).

FTW_PHYS
: If set, do not follow symbolic links. (This is what you want.) If not set, symbolic links are followed, but no file is reported twice.

  If **FTW_PHYS** is not set, but **FTW_DEPTH** is set, then the function *fn*() is never called for a directory that would be a descendant of itself.

ftw()

ftw() is an older function that offers a subset of the functionality of **nftw**(). The notable differences are as follows:

- **ftw**() has no *flags* argument. It behaves the same as when **nftw**() is called with *flags* specified as zero.
- The callback function, *fn*(), is not supplied with a fourth argument.
- The range of values that is passed via the *typeflag* argument supplied to *fn*() is smaller: just **FTW_F**, **FTW_D**, **FTW_DNR**, **FTW_NS**, and (possibly) **FTW_SL**.

RETURN VALUE

These functions return 0 on success, and −1 if an error occurs.

If *fn*() returns nonzero, then the tree walk is terminated and the value returned by *fn*() is returned as the result of **ftw**() or **nftw**().

If **nftw**() is called with the **FTW_ACTIONRETVAL** flag, then the only nonzero value that should be used by *fn*() to terminate the tree walk is **FTW_STOP**, and that value is returned as the result of **nftw**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
nftw()	Thread safety	MT-Safe cwd
ftw()	Thread safety	MT-Safe

VERSIONS

In some implementations (e.g., glibc), **ftw**() will never use **FTW_SL**; on other systems **FTW_SL** occurs only for symbolic links that do not point to an existing file; and again on other systems **ftw**() will use **FTW_SL** for each symbolic link. If *fpath* is a symbolic link and *stat*(2) failed, POSIX.1-2008 states that it is undefined whether **FTW_NS** or **FTW_SL** is passed in *typeflag*. For predictable results, use **nftw**().

STANDARDS

POSIX.1-2008.

HISTORY

ftw() POSIX.1-2001, SVr4, SUSv1. POSIX.1-2008 marks it as obsolete.

nftw() glibc 2.1. POSIX.1-2001, SUSv1.

FTW_SL
POSIX.1-2001, SUSv1.

NOTES

POSIX.1-2008 notes that the results are unspecified if *fn* does not preserve the current working directory.

BUGS

According to POSIX.1-2008, when the *typeflag* argument passed to *fn*() contains **FTW_SLN**, the buffer pointed to by *sb* should contain information about the dangling symbolic link (obtained by calling *lstat*(2) on the link). Early glibc versions correctly followed the POSIX specification on this point. However, as a result of a regression introduced in glibc 2.4, the contents of the buffer pointed to by *sb* were undefined when **FTW_SLN** is passed in *typeflag*. (More precisely, the contents of the buffer were left unchanged in this case.) This regression was eventually fixed in glibc 2.30, so that the glibc implementation (once more) follows the POSIX specification.

EXAMPLES

The following program traverses the directory tree under the path named in its first command-line argument, or under the current directory if no argument is supplied. It displays various information about each file. The second command-line argument can be used to specify characters that control the value assigned to the *flags* argument when calling **nftw**().

Program source

```
#define _XOPEN_SOURCE 500
```

```
#include <ftw.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

static int
display_info(const char *fpath, const struct stat *sb,
             int tflag, struct FTW *ftwbuf)
{
    printf("%-3s %2d ",
           (tflag == FTW_D) ?   "d"   : (tflag == FTW_DNR) ? "dnr" :
           (tflag == FTW_DP) ?  "dp"  : (tflag == FTW_F) ?   "f" :
           (tflag == FTW_NS) ?  "ns"  : (tflag == FTW_SL) ?  "sl" :
           (tflag == FTW_SLN) ? "sln" : "???",
           ftwbuf->level);

    if (tflag == FTW_NS)
        printf("-------");
    else
        printf("%7jd", (intmax_t) sb->st_size);

    printf("   %-40s %d %s\n",
           fpath, ftwbuf->base, fpath + ftwbuf->base);

    return 0;           /* To tell nftw() to continue */
}

int
main(int argc, char *argv[])
{
    int flags = 0;

    if (argc > 2 && strchr(argv[2], 'd') != NULL)
        flags |= FTW_DEPTH;
    if (argc > 2 && strchr(argv[2], 'p') != NULL)
        flags |= FTW_PHYS;

    if (nftw((argc < 2) ? "." : argv[1], display_info, 20, flags)
        == -1)
    {
        perror("nftw");
        exit(EXIT_FAILURE);
    }

    exit(EXIT_SUCCESS);
}
```

NAME

futimes, lutimes − change file timestamps

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/time.h>

int futimes(int *fd***, const struct timeval** *tv***[2]);**
int lutimes(const char * *filename***, const struct timeval** *tv***[2]);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

futimes(), **lutimes**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

futimes() changes the access and modification times of a file in the same way as *utimes*(2), with the difference that the file whose timestamps are to be changed is specified via a file descriptor, *fd*, rather than via a pathname.

lutimes() changes the access and modification times of a file in the same way as *utimes*(2), with the difference that if *filename* refers to a symbolic link, then the link is not dereferenced: instead, the timestamps of the symbolic link are changed.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

Errors are as for *utimes*(2), with the following additions for **futimes**():

EBADF
fd is not a valid file descriptor.

ENOSYS
The */proc* filesystem could not be accessed.

The following additional error may occur for **lutimes**():

ENOSYS
The kernel does not support this call; Linux 2.6.22 or later is required.

ATTRIBUTES

NAME

fwide − set and determine the orientation of a FILE stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

int fwide(FILE ****stream*, int** *mode***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fwide():
_XOPEN_SOURCE >= 500 || _ISOC99_SOURCE
|| _POSIX_C_SOURCE >= 200112L

DESCRIPTION

When *mode* is zero, the **fwide**() function determines the current orientation of *stream*. It returns a positive value if *stream* is wide-character oriented, that is, if wide-character I/O is permitted but char I/O is disallowed. It returns a negative value if *stream* is byte oriented—that is, if char I/O is permitted but wide-character I/O is disallowed. It returns zero if *stream* has no orientation yet; in this case the next I/O operation might change the orientation (to byte oriented if it is a char I/O operation, or to wide-character oriented if it is a wide-character I/O operation).

Once a stream has an orientation, it cannot be changed and persists until the stream is closed.

When *mode* is nonzero, the **fwide**() function first attempts to set *stream*'s orientation (to wide-character oriented if *mode* is greater than 0, or to byte oriented if *mode* is less than 0). It then returns a value denoting the current orientation, as above.

RETURN VALUE

The **fwide**() function returns the stream's orientation, after possibly changing it. A positive return value means wide-character oriented. A negative return value means byte oriented. A return value of zero means undecided.

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

Wide-character output to a byte oriented stream can be performed through the *fprintf*(3) function with the **%lc** and **%ls** directives.

Char oriented output to a wide-character oriented stream can be performed through the *fwprintf*(3) function with the **%c** and **%s** directives.

SEE ALSO

fprintf(3), *fwprintf*(3)

NAME

gamma, gammaf, gammal − (logarithm of the) gamma function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

[[deprecated]] double gamma(double x);
[[deprecated]] float gammaf(float x);
[[deprecated]] long double gammal(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

gamma():
_XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

gammaf(), **gammal**():
_XOPEN_SOURCE >= 600 || (_XOPEN_SOURCE && _ISOC99_SOURCE)
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions are deprecated: instead, use either the *tgamma*(3) or the *lgamma*(3) functions, as appropriate.

For the definition of the Gamma function, see *tgamma*(3).

***BSD version**

The libm in 4.4BSD and some versions of FreeBSD had a **gamma**() function that computes the Gamma function, as one would expect.

glibc version

glibc has a **gamma**() function that is equivalent to *lgamma*(3) and computes the natural logarithm of the Gamma function.

RETURN VALUE

See *lgamma*(3).

ERRORS

See *lgamma*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gamma(), **gammaf**(), **gammal**()	Thread safety	MT-Unsafe race:signgam

STANDARDS

None.

HISTORY

SVID 2.

Because of historical variations in behavior across systems, this function is not specified in any recent standard.

4.2BSD had a **gamma**() that computed ln(|Gamma(|*x*|)|), leaving the sign of Gamma(|*x*|) in the external integer *signgam*. In 4.3BSD the name was changed to *lgamma*(3), and the man page promises

> "At some time in the future the name gamma will be rehabilitated and used for the Gamma function"

This did indeed happen in 4.4BSD, where **gamma**() computes the Gamma function (with no effect on *signgam*). However, this came too late, and we now have *tgamma*(3), the "true gamma" function.

SEE ALSO

lgamma(3), *signgam*(3), *tgamma*(3)

NAME

gcvt − convert a floating-point number to a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

char *gcvt(double number, int ndigit, char *buf);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

gcvt():
- Since glibc 2.17
  - (_XOPEN_SOURCE >= 500 && ! (_POSIX_C_SOURCE >= 200809L))
    - || /* glibc >= 2.20 */ _DEFAULT_SOURCE
    - || /* glibc <= 2.19 */ _SVID_SOURCE
- glibc 2.12 to glibc 2.16:
  - (_XOPEN_SOURCE >= 500 && ! (_POSIX_C_SOURCE >= 200112L))
    - || _SVID_SOURCE
- Before glibc 2.12:
  - _SVID_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

The **gcvt**() function converts *number* to a minimal length null-terminated ASCII string and stores the result in *buf*. It produces *ndigit* significant digits in either *printf*(3) F format or E format.

RETURN VALUE

The **gcvt**() function returns *buf*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gcvt()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

Marked as LEGACY in POSIX.1-2001. POSIX.1-2008 removed it, recommending the use of *sprintf*(3) instead (though *snprintf*(3) may be preferable).

SEE ALSO

ecvt(3), *fcvt*(3), *sprintf*(3)

NAME

_Generic − type-generic selection

SYNOPSIS

_Generic(*expression***, type1:** e1**, ...** /***, default:** e */**);**

DESCRIPTION

_Generic() evaluates the path of code under the type selector that is compatible with the type of the controlling *expression*, or **default:** if no type is compatible.

expression is not evaluated.

This is especially useful for writing type-generic macros, that will behave differently depending on the type of the argument.

STANDARDS

C11.

HISTORY

C11.

EXAMPLES

The following program demonstrates how to write a replacement for the standard *imaxabs*(3) function, which being a function can't really provide what it promises: seamlessly upgrading to the widest available type.

```
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>

#define my_imaxabs  _Generic(INTMAX_C(0),  \
    long:           labs,                  \
    long long:      llabs                  \
/*  long long long: lllabs */              \
)

int
main(void)
{
    off_t  a;

    a = -42;
    printf("imaxabs(%jd) == %jd\n", (intmax_t) a, my_imaxabs(a));
    printf("&imaxabs == %p\n", &my_imaxabs);
    printf("&labs    == %p\n", &labs);
    printf("&llabs   == %p\n", &llabs);

    exit(EXIT_SUCCESS);
}
```

NAME

get_nprocs, get_nprocs_conf − get number of processors

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/sysinfo.h>

int get_nprocs(void);
int get_nprocs_conf(void);

DESCRIPTION

The function **get_nprocs_conf**() returns the number of processors configured by the operating system.

The function **get_nprocs**() returns the number of processors currently available in the system. This may be less than the number returned by **get_nprocs_conf**() because processors may be offline (e.g., on hotpluggable systems).

RETURN VALUE

As given in DESCRIPTION.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
get_nprocs(), **get_nprocs_conf**()	Thread safety	MT-Safe

STANDARDS

GNU.

NOTES

The current implementation of these functions is rather expensive, since they open and parse files in the */sys* filesystem each time they are called.

The following *sysconf*(3) calls make use of the functions documented on this page to return the same information.

```
np = sysconf(_SC_NPROCESSORS_CONF);     /* processors configured */
np = sysconf(_SC_NPROCESSORS_ONLN);     /* processors available */
```

EXAMPLES

The following example shows how **get_nprocs**() and **get_nprocs_conf**() can be used.

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/sysinfo.h>

int
main(void)
{
    printf("This system has %d processors configured and "
           "%d processors available.\n",
           get_nprocs_conf(), get_nprocs());
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

nproc(1)

NAME

get_phys_pages, get_avphys_pages − get total and available physical page counts

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/sysinfo.h>

long get_phys_pages(void);
long get_avphys_pages(void);

DESCRIPTION

The function **get_phys_pages**() returns the total number of physical pages of memory available on the system.

The function **get_avphys_pages**() returns the number of currently available physical pages of memory on the system.

RETURN VALUE

On success, these functions return a nonnegative value as given in DESCRIPTION. On failure, they return −1 and set *errno* to indicate the error.

ERRORS

ENOSYS

The system could not provide the required information (possibly because the */proc* filesystem was not mounted).

STANDARDS

GNU.

HISTORY

Before glibc 2.23, these functions obtained the required information by scanning the *MemTotal* and *MemFree* fields of */proc/meminfo*. Since glibc 2.23, these functions obtain the required information by calling *sysinfo*(2).

NOTES

The following *sysconf*(3) calls provide a portable means of obtaining the same information as the functions described on this page.

```
total_pages = sysconf(_SC_PHYS_PAGES);    /* total pages */
avl_pages = sysconf(_SC_AVPHYS_PAGES);    /* available pages */
```

EXAMPLES

The following example shows how **get_phys_pages**() and **get_avphys_pages**() can be used.

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/sysinfo.h>

int
main(void)
{
    printf("This system has %ld pages of physical memory and "
           "%ld pages of physical memory available.\n",
           get_phys_pages(), get_avphys_pages());
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

sysconf(3)

NAME

getaddrinfo, freeaddrinfo, gai_strerror − network address and service translation

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *restrict node,
                const char *restrict service,
                const struct addrinfo *restrict hints,
                struct addrinfo **restrict res);

void freeaddrinfo(struct addrinfo *res);

const char *gai_strerror(int errcode);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getaddrinfo(), **freeaddrinfo**(), **gai_strerror**():
Since glibc 2.22:
_POSIX_C_SOURCE >= 200112L
glibc 2.21 and earlier:
_POSIX_C_SOURCE

DESCRIPTION

Given *node* and *service*, which identify an Internet host and a service, **getaddrinfo**() returns one or more *addrinfo* structures, each of which contains an Internet address that can be specified in a call to *bind*(2) or *connect*(2). The **getaddrinfo**() function combines the functionality provided by the *gethostbyname*(3) and *getservbyname*(3) functions into a single interface, but unlike the latter functions, **getaddrinfo**() is reentrant and allows programs to eliminate IPv4-versus-IPv6 dependencies.

The *addrinfo* structure used by **getaddrinfo**() contains the following fields:

```
struct addrinfo {
    int              ai_flags;
    int              ai_family;
    int              ai_socktype;
    int              ai_protocol;
    socklen_t        ai_addrlen;
    struct sockaddr *ai_addr;
    char            *ai_canonname;
    struct addrinfo *ai_next;
};
```

The *hints* argument points to an *addrinfo* structure that specifies criteria for selecting the socket address structures returned in the list pointed to by *res*. If *hints* is not NULL it points to an *addrinfo* structure whose *ai_family*, *ai_socktype*, and *ai_protocol* specify criteria that limit the set of socket addresses returned by **getaddrinfo**(), as follows:

ai_family
: This field specifies the desired address family for the returned addresses. Valid values for this field include **AF_INET** and **AF_INET6**. The value **AF_UNSPEC** indicates that **getaddrinfo**() should return socket addresses for any address family (either IPv4 or IPv6, for example) that can be used with *node* and *service*.

ai_socktype
: This field specifies the preferred socket type, for example **SOCK_STREAM** or **SOCK_DGRAM**. Specifying 0 in this field indicates that socket addresses of any type can be returned by **getaddrinfo**().

ai_protocol
: This field specifies the protocol for the returned socket addresses. Specifying 0 in this field indicates that socket addresses with any protocol can be returned by **getaddrinfo**().

ai_flags
: This field specifies additional options, described below. Multiple flags are specified by bitwise OR-ing them together.

All the other fields in the structure pointed to by *hints* must contain either 0 or a null pointer, as appropriate.

Specifying *hints* as NULL is equivalent to setting *ai_socktype* and *ai_protocol* to 0; *ai_family* to **AF_UNSPEC**; and *ai_flags* to **(AI_V4MAPPED | AI_ADDRCONFIG)**. (POSIX specifies different defaults for *ai_flags*; see NOTES.) *node* specifies either a numerical network address (for IPv4, numbers-and-dots notation as supported by *inet_aton*(3); for IPv6, hexadecimal string format as supported by *inet_pton*(3)), or a network hostname, whose network addresses are looked up and resolved. If *hints.ai_flags* contains the **AI_NUMERICHOST** flag, then *node* must be a numerical network address. The **AI_NUMERICHOST** flag suppresses any potentially lengthy network host address lookups.

If the **AI_PASSIVE** flag is specified in *hints.ai_flags*, and *node* is NULL, then the returned socket addresses will be suitable for *bind*(2)ing a socket that will *accept*(2) connections. The returned socket address will contain the "wildcard address" (**INADDR_ANY** for IPv4 addresses, **IN6ADDR_ANY_INIT** for IPv6 address). The wildcard address is used by applications (typically servers) that intend to accept connections on any of the host's network addresses. If *node* is not NULL, then the **AI_PASSIVE** flag is ignored.

If the **AI_PASSIVE** flag is not set in *hints.ai_flags*, then the returned socket addresses will be suitable for use with *connect*(2), *sendto*(2), or *sendmsg*(2). If *node* is NULL, then the network address will be set to the loopback interface address (**INADDR_LOOPBACK** for IPv4 addresses, **IN6ADDR_LOOPBACK_INIT** for IPv6 address); this is used by applications that intend to communicate with peers running on the same host.

service sets the port in each returned address structure. If this argument is a service name (see *services*(5)), it is translated to the corresponding port number. This argument can also be specified as a decimal number, which is simply converted to binary. If *service* is NULL, then the port number of the returned socket addresses will be left uninitialized. If **AI_NUMERICSERV** is specified in *hints.ai_flags* and *service* is not NULL, then *service* must point to a string containing a numeric port number. This flag is used to inhibit the invocation of a name resolution service in cases where it is known not to be required.

Either *node* or *service*, but not both, may be NULL.

The **getaddrinfo**() function allocates and initializes a linked list of *addrinfo* structures, one for each network address that matches *node* and *service*, subject to any restrictions imposed by *hints*, and returns a pointer to the start of the list in *res*. The items in the linked list are linked by the *ai_next* field.

There are several reasons why the linked list may have more than one *addrinfo* structure, including: the network host is multihomed, accessible over multiple protocols (e.g., both **AF_INET** and **AF_INET6**); or the same service is available from multiple socket types (one **SOCK_STREAM** address and another **SOCK_DGRAM** address, for example). Normally, the application should try using the addresses in the order in which they are returned. The sorting function used within **getaddrinfo**() is defined in RFC 3484; the order can be tweaked for a particular system by editing */etc/gai.conf* (available since glibc 2.5).

If *hints.ai_flags* includes the **AI_CANONNAME** flag, then the *ai_canonname* field of the first of the *addrinfo* structures in the returned list is set to point to the official name of the host.

The remaining fields of each returned *addrinfo* structure are initialized as follows:

- The *ai_family*, *ai_socktype*, and *ai_protocol* fields return the socket creation parameters (i.e., these fields have the same meaning as the corresponding arguments of *socket*(2)). For example, *ai_family* might return **AF_INET** or **AF_INET6**; *ai_socktype* might return **SOCK_DGRAM** or **SOCK_STREAM**; and *ai_protocol* returns the protocol for the socket.
- A pointer to the socket address is placed in the *ai_addr* field, and the length of the socket address, in bytes, is placed in the *ai_addrlen* field.

If *hints.ai_flags* includes the **AI_ADDRCONFIG** flag, then IPv4 addresses are returned in the list pointed to by *res* only if the local system has at least one IPv4 address configured, and IPv6 addresses

are returned only if the local system has at least one IPv6 address configured. The loopback address is not considered for this case as valid as a configured address. This flag is useful on, for example, IPv4-only systems, to ensure that **getaddrinfo**() does not return IPv6 socket addresses that would always fail in *connect*(2) or *bind*(2).

If *hints.ai_flags* specifies the **AI_V4MAPPED** flag, and *hints.ai_family* was specified as **AF_INET6**, and no matching IPv6 addresses could be found, then return IPv4-mapped IPv6 addresses in the list pointed to by *res*. If both **AI_V4MAPPED** and **AI_ALL** are specified in *hints.ai_flags*, then return both IPv6 and IPv4-mapped IPv6 addresses in the list pointed to by *res*. **AI_ALL** is ignored if **AI_V4MAPPED** is not also specified.

The **freeaddrinfo**() function frees the memory that was allocated for the dynamically allocated linked list *res*.

Extensions to getaddrinfo() for Internationalized Domain Names

Starting with glibc 2.3.4, **getaddrinfo**() has been extended to selectively allow the incoming and outgoing hostnames to be transparently converted to and from the Internationalized Domain Name (IDN) format (see RFC 3490, *Internationalizing Domain Names in Applications (IDNA)*). Four new flags are defined:

AI_IDN
: If this flag is specified, then the node name given in *node* is converted to IDN format if necessary. The source encoding is that of the current locale.

  If the input name contains non-ASCII characters, then the IDN encoding is used. Those parts of the node name (delimited by dots) that contain non-ASCII characters are encoded using ASCII Compatible Encoding (ACE) before being passed to the name resolution functions.

AI_CANONIDN
: After a successful name lookup, and if the **AI_CANONNAME** flag was specified, **getaddrinfo**() will return the canonical name of the node corresponding to the *addrinfo* structure value passed back. The return value is an exact copy of the value returned by the name resolution function.

  If the name is encoded using ACE, then it will contain the *xn−−* prefix for one or more components of the name. To convert these components into a readable form the **AI_CANONIDN** flag can be passed in addition to **AI_CANONNAME**. The resulting string is encoded using the current locale's encoding.

AI_IDN_ALLOW_UNASSIGNED
AI_IDN_USE_STD3_ASCII_RULES
: Setting these flags will enable the IDNA_ALLOW_UNASSIGNED (allow unassigned Unicode code points) and IDNA_USE_STD3_ASCII_RULES (check output to make sure it is a STD3 conforming hostname) flags respectively to be used in the IDNA handling.

RETURN VALUE

getaddrinfo() returns 0 if it succeeds, or one of the following nonzero error codes:

EAI_ADDRFAMILY
: The specified network host does not have any network addresses in the requested address family.

EAI_AGAIN
: The name server returned a temporary failure indication. Try again later.

EAI_BADFLAGS
: *hints.ai_flags* contains invalid flags; or, *hints.ai_flags* included **AI_CANONNAME** and *node* was NULL.

EAI_FAIL
: The name server returned a permanent failure indication.

EAI_FAMILY
: The requested address family is not supported.

EAI_MEMORY
: Out of memory.

EAI_NODATA
The specified network host exists, but does not have any network addresses defined.

EAI_NONAME
The *node* or *service* is not known; or both *node* and *service* are NULL; or **AI_NUMERICSERV** was specified in *hints.ai_flags* and *service* was not a numeric port-number string.

EAI_SERVICE
The requested service is not available for the requested socket type. It may be available through another socket type. For example, this error could occur if *service* was "shell" (a service available only on stream sockets), and either *hints.ai_protocol* was **IPPROTO_UDP**, or *hints.ai_socktype* was **SOCK_DGRAM**; or the error could occur if *service* was not NULL, and *hints.ai_socktype* was **SOCK_RAW** (a socket type that does not support the concept of services).

EAI_SOCKTYPE
The requested socket type is not supported. This could occur, for example, if *hints.ai_socktype* and *hints.ai_protocol* are inconsistent (e.g., **SOCK_DGRAM** and **IPPROTO_TCP**, respectively).

EAI_SYSTEM
Other system error; *errno* is set to indicate the error.

The **gai_strerror**() function translates these error codes to a human readable string, suitable for error reporting.

FILES

/etc/gai.conf

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getaddrinfo()	Thread safety	MT-Safe env locale
freeaddrinfo(), **gai_strerror**()	Thread safety	MT-Safe

VERSIONS

According to POSIX.1, specifying *hints* as NULL should cause *ai_flags* to be assumed as 0. The GNU C library instead assumes a value of **(AI_V4MAPPED | AI_ADDRCONFIG)** for this case, since this value is considered an improvement on the specification.

STANDARDS

POSIX.1-2008.

getaddrinfo()
RFC 2553.

HISTORY

POSIX.1-2001.

AI_ADDRCONFIG
AI_ALL
AI_V4MAPPED
glibc 2.3.3.

AI_NUMERICSERV
glibc 2.3.4.

NOTES

getaddrinfo() supports the *address***%***scope-id* notation for specifying the IPv6 scope-ID.

EXAMPLES

The following programs demonstrate the use of **getaddrinfo**(), **gai_strerror**(), **freeaddrinfo**(), and *getnameinfo*(3). The programs are an echo server and client for UDP datagrams.

Server program

```
#include <netdb.h>
#include <stdio.h>
```

```
#include <stdlib.h>
#include <string.h>
#include <sys/socket.h>
#include <sys/types.h>
#include <unistd.h>

#define BUF_SIZE 500

int
main(int argc, char *argv[])
{
    int                     sfd, s;
    char                    buf[BUF_SIZE];
    ssize_t                 nread;
    socklen_t               peer_addrlen;
    struct addrinfo         hints;
    struct addrinfo         *result, *rp;
    struct sockaddr_storage  peer_addr;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s port\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    memset(&hints, 0, sizeof(hints));
    hints.ai_family = AF_UNSPEC;    /* Allow IPv4 or IPv6 */
    hints.ai_socktype = SOCK_DGRAM; /* Datagram socket */
    hints.ai_flags = AI_PASSIVE;    /* For wildcard IP address */
    hints.ai_protocol = 0;          /* Any protocol */
    hints.ai_canonname = NULL;
    hints.ai_addr = NULL;
    hints.ai_next = NULL;

    s = getaddrinfo(NULL, argv[1], &hints, &result);
    if (s != 0) {
        fprintf(stderr, "getaddrinfo: %s\n", gai_strerror(s));
        exit(EXIT_FAILURE);
    }

    /* getaddrinfo() returns a list of address structures.
       Try each address until we successfully bind(2).
       If socket(2) (or bind(2)) fails, we (close the socket
       and) try the next address. */

    for (rp = result; rp != NULL; rp = rp->ai_next) {
        sfd = socket(rp->ai_family, rp->ai_socktype,
                     rp->ai_protocol);
        if (sfd == -1)
            continue;

        if (bind(sfd, rp->ai_addr, rp->ai_addrlen) == 0)
            break;                  /* Success */

        close(sfd);
    }

    freeaddrinfo(result);           /* No longer needed */

    if (rp == NULL) {               /* No address succeeded */
```

```
            fprintf(stderr, "Could not bind\n");
            exit(EXIT_FAILURE);
        }

        /* Read datagrams and echo them back to sender. */

        for (;;) {
            char host[NI_MAXHOST], service[NI_MAXSERV];

            peer_addrlen = sizeof(peer_addr);
            nread = recvfrom(sfd, buf, BUF_SIZE, 0,
                             (struct sockaddr *) &peer_addr, &peer_addrlen);
            if (nread == -1)
                continue;               /* Ignore failed request */

            s = getnameinfo((struct sockaddr *) &peer_addr,
                            peer_addrlen, host, NI_MAXHOST,
                            service, NI_MAXSERV, NI_NUMERICSERV);
            if (s == 0)
                printf("Received %zd bytes from %s:%s\n",
                       nread, host, service);
            else
                fprintf(stderr, "getnameinfo: %s\n", gai_strerror(s));

            if (sendto(sfd, buf, nread, 0, (struct sockaddr *) &peer_addr,
                       peer_addrlen) != nread)
            {
                fprintf(stderr, "Error sending response\n");
            }
        }
    }
```

Client program

```
    #include <netdb.h>
    #include <stdio.h>
    #include <stdlib.h>
    #include <string.h>
    #include <sys/socket.h>
    #include <sys/types.h>
    #include <unistd.h>

    #define BUF_SIZE 500

NAME

getaddrinfo_a, gai_suspend, gai_error, gai_cancel − asynchronous network address and service translation

LIBRARY

Asynchronous name lookup library (*libanl*, *−lanl*)

SYNOPSIS

```
#define _GNU_SOURCE       /* See feature_test_macros(7) */
#include <netdb.h>

int getaddrinfo_a(int mode, struct gaicb *list[restrict],
                  int nitems, struct sigevent *restrict sevp);
int gai_suspend(const struct gaicb *const list[], int nitems,
                  const struct timespec *timeout);

int gai_error(struct gaicb *req);
int gai_cancel(struct gaicb *req);
```

DESCRIPTION

The **getaddrinfo_a**() function performs the same task as *getaddrinfo*(3), but allows multiple name look-ups to be performed asynchronously, with optional notification on completion of look-up operations.

The *mode* argument has one of the following values:

GAI_WAIT
: Perform the look-ups synchronously. The call blocks until the look-ups have completed.

GAI_NOWAIT
: Perform the look-ups asynchronously. The call returns immediately, and the requests are resolved in the background. See the discussion of the *sevp* argument below.

The array *list* specifies the look-up requests to process. The *nitems* argument specifies the number of elements in *list*. The requested look-up operations are started in parallel. NULL elements in *list* are ignored. Each request is described by a *gaicb* structure, defined as follows:

```
struct gaicb {
    const char            *ar_name;
    const char            *ar_service;
    const struct addrinfo *ar_request;
    struct addrinfo       *ar_result;
};
```

The elements of this structure correspond to the arguments of *getaddrinfo*(3). Thus, *ar_name* corresponds to the *node* argument and *ar_service* to the *service* argument, identifying an Internet host and a service. The *ar_request* element corresponds to the *hints* argument, specifying the criteria for selecting the returned socket address structures. Finally, *ar_result* corresponds to the *res* argument; you do not need to initialize this element, it will be automatically set when the request is resolved. The *addrinfo* structure referenced by the last two elements is described in *getaddrinfo*(3).

When *mode* is specified as **GAI_NOWAIT**, notifications about resolved requests can be obtained by employing the *sigevent* structure pointed to by the *sevp* argument. For the definition and general details of this structure, see *sigevent*(3type). The *sevp−>sigev_notify* field can have the following values:

SIGEV_NONE
: Don't provide any notification.

SIGEV_SIGNAL
: When a look-up completes, generate the signal *sigev_signo* for the process. See *sigevent*(3type) for general details. The *si_code* field of the *siginfo_t* structure will be set to **SI_ASYNCNL**.

SIGEV_THREAD
: When a look-up completes, invoke *sigev_notify_function* as if it were the start function of a new thread. See *sigevent*(3type) for details.

For **SIGEV_SIGNAL** and **SIGEV_THREAD**, it may be useful to point *sevp−>sigev_value.sival_ptr*

to *list*.

The **gai_suspend**() function suspends execution of the calling thread, waiting for the completion of one or more requests in the array *list*. The *nitems* argument specifies the size of the array *list*. The call blocks until one of the following occurs:

- One or more of the operations in *list* completes.
- The call is interrupted by a signal that is caught.
- The time interval specified in *timeout* elapses. This argument specifies a timeout in seconds plus nanoseconds (see *nanosleep*(2) for details of the *timespec* structure). If *timeout* is NULL, then the call blocks indefinitely (until one of the events above occurs).

No explicit indication of which request was completed is given; you must determine which request(s) have completed by iterating with **gai_error**() over the list of requests.

The **gai_error**() function returns the status of the request *req*: either **EAI_INPROGRESS** if the request was not completed yet, 0 if it was handled successfully, or an error code if the request could not be resolved.

The **gai_cancel**() function cancels the request *req*. If the request has been canceled successfully, the error status of the request will be set to **EAI_CANCELED** and normal asynchronous notification will be performed. The request cannot be canceled if it is currently being processed; in that case, it will be handled as if **gai_cancel**() has never been called. If *req* is NULL, an attempt is made to cancel all outstanding requests that the process has made.

RETURN VALUE

The **getaddrinfo_a**() function returns 0 if all of the requests have been enqueued successfully, or one of the following nonzero error codes:

EAI_AGAIN
: The resources necessary to enqueue the look-up requests were not available. The application may check the error status of each request to determine which ones failed.

EAI_MEMORY
: Out of memory.

EAI_SYSTEM
: *mode* is invalid.

The **gai_suspend**() function returns 0 if at least one of the listed requests has been completed. Otherwise, it returns one of the following nonzero error codes:

EAI_AGAIN
: The given timeout expired before any of the requests could be completed.

EAI_ALLDONE
: There were no actual requests given to the function.

EAI_INTR
: A signal has interrupted the function. Note that this interruption might have been caused by signal notification of some completed look-up request.

The **gai_error**() function can return **EAI_INPROGRESS** for an unfinished look-up request, 0 for a successfully completed look-up (as described above), one of the error codes that could be returned by *getaddrinfo*(3), or the error code **EAI_CANCELED** if the request has been canceled explicitly before it could be finished.

The **gai_cancel**() function can return one of these values:

EAI_CANCELED
: The request has been canceled successfully.

EAI_NOTCANCELED
: The request has not been canceled.

EAI_ALLDONE
: The request has already completed.

The *gai_strerror*(3) function translates these error codes to a human readable string, suitable for error

reporting.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getaddrinfo_a(), **gai_suspend**(), **gai_error**(), **gai_cancel**()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.2.3.

The interface of **getaddrinfo_a**() was modeled after the *lio_listio*(3) interface.

EXAMPLES

Two examples are provided: a simple example that resolves several requests in parallel synchronously, and a complex example showing some of the asynchronous capabilities.

Synchronous example

The program below simply resolves several hostnames in parallel, giving a speed-up compared to resolving the hostnames sequentially using *getaddrinfo*(3). The program might be used like this:

```
$ ./a.out mirrors.kernel.org enoent.linuxfoundation.org gnu.org
mirrors.kernel.org: 139.178.88.99
enoent.linuxfoundation.org: Name or service not known
gnu.org: 209.51.188.116
```

Here is the program source code

```
#define _GNU_SOURCE
#include <err.h>
#include <netdb.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define MALLOC(n, type)  ((type *) reallocarray(NULL, n, sizeof(type)))

int
main(int argc, char *argv[])
{
    int ret;
    struct gaicb *reqs[argc - 1];
    char host[NI_MAXHOST];
    struct addrinfo *res;

    if (argc < 2) {
        fprintf(stderr, "Usage: %s HOST...\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    for (size_t i = 0; i < argc - 1; i++) {
        reqs[i] = MALLOC(1, struct gaicb);
        if (reqs[i] == NULL)
            err(EXIT_FAILURE, "malloc");

        memset(reqs[i], 0, sizeof(*reqs[0]));
        reqs[i]->ar_name = argv[i + 1];
    }

    ret = getaddrinfo_a(GAI_WAIT, reqs, argc - 1, NULL);
    if (ret != 0) {
        fprintf(stderr, "getaddrinfo_a() failed: %s\n",
```

```
                gai_strerror(ret));
            exit(EXIT_FAILURE);
        }

        for (size_t i = 0; i < argc - 1; i++) {
            printf("%s: ", reqs[i]->ar_name);
            ret = gai_error(reqs[i]);
            if (ret == 0) {
                res = reqs[i]->ar_result;

                ret = getnameinfo(res->ai_addr, res->ai_addrlen,
                                  host, sizeof(host),
                                  NULL, 0, NI_NUMERICHOST);
                if (ret != 0) {
                    fprintf(stderr, "getnameinfo() failed: %s\n",
                            gai_strerror(ret));
                    exit(EXIT_FAILURE);
                }
                puts(host);

            } else {
                puts(gai_strerror(ret));
            }
        }
        exit(EXIT_SUCCESS);
    }
```

Asynchronous example

This example shows a simple interactive **getaddrinfo_a**() front-end. The notification facility is not demonstrated.

An example session might look like this:

```
$ ./a.out
> a mirrors.kernel.org enoent.linuxfoundation.org gnu.org
> c 2
[2] gnu.org: Request not canceled
> w 0 1
[00] mirrors.kernel.org: Finished
> l
[00] mirrors.kernel.org: 139.178.88.99
[01] enoent.linuxfoundation.org: Processing request in progress
[02] gnu.org: 209.51.188.116
> l
[00] mirrors.kernel.org: 139.178.88.99
[01] enoent.linuxfoundation.org: Name or service not known
[02] gnu.org: 209.51.188.116
```

The program source is as follows:

```
#define _GNU_SOURCE
#include <assert.h>
#include <err.h>
#include <netdb.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

NAME

getauxval − retrieve a value from the auxiliary vector

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/auxv.h>

unsigned long getauxval(unsigned long *type***);**

DESCRIPTION

The **getauxval**() function retrieves values from the auxiliary vector, a mechanism that the kernel's ELF binary loader uses to pass certain information to user space when a program is executed.

Each entry in the auxiliary vector consists of a pair of values: a type that identifies what this entry represents, and a value for that type. Given the argument *type*, **getauxval**() returns the corresponding value.

The value returned for each *type* is given in the following list. Not all *type* values are present on all architectures.

AT_BASE
: The base address of the program interpreter (usually, the dynamic linker).

AT_BASE_PLATFORM
: A pointer to a string (PowerPC and MIPS only). On PowerPC, this identifies the real platform; may differ from **AT_PLATFORM**. On MIPS, this identifies the ISA level (since Linux 5.7).

AT_CLKTCK
: The frequency with which *times*(2) counts. This value can also be obtained via *sysconf(_SC_CLK_TCK)*.

AT_DCACHEBSIZE
: The data cache block size.

AT_EGID
: The effective group ID of the thread.

AT_ENTRY
: The entry address of the executable.

AT_EUID
: The effective user ID of the thread.

AT_EXECFD
: File descriptor of program.

AT_EXECFN
: A pointer to a string containing the pathname used to execute the program.

AT_FLAGS
: Flags (unused).

AT_FPUCW
: Used FPU control word (SuperH architecture only). This gives some information about the FPU initialization performed by the kernel.

AT_GID
: The real group ID of the thread.

AT_HWCAP
: An architecture and ABI dependent bit-mask whose settings indicate detailed processor capabilities. The contents of the bit mask are hardware dependent (for example, see the kernel source file *arch/x86/include/asm/cpufeature.h* for details relating to the Intel x86 architecture; the value returned is the first 32-bit word of the array described there). A human-readable version of the same information is available via */proc/cpuinfo*.

AT_HWCAP2 (since glibc 2.18)
Further machine-dependent hints about processor capabilities.

AT_ICACHEBSIZE
The instruction cache block size.

AT_L1D_CACHEGEOMETRY
Geometry of the L1 data cache, encoded with the cache line size in bytes in the bottom 16 bits and the cache associativity in the next 16 bits. The associativity is such that if N is the 16-bit value, the cache is N-way set associative.

AT_L1D_CACHESIZE
The L1 data cache size.

AT_L1I_CACHEGEOMETRY
Geometry of the L1 instruction cache, encoded as for **AT_L1D_CACHEGEOMETRY**.

AT_L1I_CACHESIZE
The L1 instruction cache size.

AT_L2_CACHEGEOMETRY
Geometry of the L2 cache, encoded as for **AT_L1D_CACHEGEOMETRY**.

AT_L2_CACHESIZE
The L2 cache size.

AT_L3_CACHEGEOMETRY
Geometry of the L3 cache, encoded as for **AT_L1D_CACHEGEOMETRY**.

AT_L3_CACHESIZE
The L3 cache size.

AT_PAGESZ
The system page size (the same value returned by *sysconf(_SC_PAGESIZE)*).

AT_PHDR
The address of the program headers of the executable.

AT_PHENT
The size of program header entry.

AT_PHNUM
The number of program headers.

AT_PLATFORM
A pointer to a string that identifies the hardware platform that the program is running on. The dynamic linker uses this in the interpretation of *rpath* values.

AT_RANDOM
The address of sixteen bytes containing a random value.

AT_SECURE
Has a nonzero value if this executable should be treated securely. Most commonly, a nonzero value indicates that the process is executing a set-user-ID or set-group-ID binary (so that its real and effective UIDs or GIDs differ from one another), or that it gained capabilities by executing a binary file that has capabilities (see *capabilities*(7)). Alternatively, a nonzero value may be triggered by a Linux Security Module. When this value is nonzero, the dynamic linker disables the use of certain environment variables (see *ld-linux.so*(8)) and glibc changes other aspects of its behavior. (See also *secure_getenv*(3).)

AT_SYSINFO
The entry point to the system call function in the vDSO. Not present/needed on all architectures (e.g., absent on x86-64).

AT_SYSINFO_EHDR
The address of a page containing the virtual Dynamic Shared Object (vDSO) that the kernel creates in order to provide fast implementations of certain system calls.

AT_UCACHEBSIZE
The unified cache block size.

AT_UID
The real user ID of the thread.

RETURN VALUE

On success, **getauxval**() returns the value corresponding to *type*. If *type* is not found, 0 is returned.

ERRORS

ENOENT (since glibc 2.19)
No entry corresponding to *type* could be found in the auxiliary vector.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getauxval()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.16.

NOTES

The primary consumer of the information in the auxiliary vector is the dynamic linker, *ld-linux.so*(8). The auxiliary vector is a convenient and efficient shortcut that allows the kernel to communicate a certain set of standard information that the dynamic linker usually or always needs. In some cases, the same information could be obtained by system calls, but using the auxiliary vector is cheaper.

The auxiliary vector resides just above the argument list and environment in the process address space. The auxiliary vector supplied to a program can be viewed by setting the **LD_SHOW_AUXV** environment variable when running a program:

```
$ LD_SHOW_AUXV=1 sleep 1
```

The auxiliary vector of any process can (subject to file permissions) be obtained via */proc/*pid*/auxv*; see *proc*(5) for more information.

BUGS

Before the addition of the **ENOENT** error in glibc 2.19, there was no way to unambiguously distinguish the case where *type* could not be found from the case where the value corresponding to *type* was zero.

NAME

getcontext, setcontext − get or set the user context

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <ucontext.h>

int getcontext(ucontext_t *_ucp_);
int setcontext(const ucontext_t *_ucp_);

DESCRIPTION

In a System V-like environment, one has the two types *mcontext_t* and *ucontext_t* defined in <*ucontext.h*> and the four functions **getcontext**(), **setcontext**(), *makecontext*(3), and *swapcontext*(3) that allow user-level context switching between multiple threads of control within a process.

The *mcontext_t* type is machine-dependent and opaque. The *ucontext_t* type is a structure that has at least the following fields:

```
typedef struct ucontext_t {
    struct ucontext_t *uc_link;
    sigset_t          uc_sigmask;
    stack_t           uc_stack;
    mcontext_t        uc_mcontext;
    ...
} ucontext_t;
```

with *sigset_t* and *stack_t* defined in <*signal.h*>. Here *uc_link* points to the context that will be resumed when the current context terminates (in case the current context was created using *makecontext*(3)), *uc_sigmask* is the set of signals blocked in this context (see *sigprocmask*(2)), *uc_stack* is the stack used by this context (see *sigaltstack*(2)), and *uc_mcontext* is the machine-specific representation of the saved context, that includes the calling thread's machine registers.

The function **getcontext**() initializes the structure pointed to by *ucp* to the currently active context.

The function **setcontext**() restores the user context pointed to by *ucp*. A successful call does not return. The context should have been obtained by a call of **getcontext**(), or *makecontext*(3), or received as the third argument to a signal handler (see the discussion of the **SA_SIGINFO** flag in *sigaction*(2)).

If the context was obtained by a call of **getcontext**(), program execution continues as if this call just returned.

If the context was obtained by a call of *makecontext*(3), program execution continues by a call to the function *func* specified as the second argument of that call to *makecontext*(3). When the function *func* returns, we continue with the *uc_link* member of the structure *ucp* specified as the first argument of that call to *makecontext*(3). When this member is NULL, the thread exits.

If the context was obtained by a call to a signal handler, then old standard text says that "program execution continues with the program instruction following the instruction interrupted by the signal". However, this sentence was removed in SUSv2, and the present verdict is "the result is unspecified".

RETURN VALUE

When successful, **getcontext**() returns 0 and **setcontext**() does not return. On error, both return −1 and set *errno* to indicate the error.

ERRORS

None defined.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getcontext(), **setcontext**()	Thread safety	MT-Safe race:ucp

STANDARDS

None.

HISTORY

SUSv2, POSIX.1-2001.

POSIX.1-2008 removes these functions, citing portability issues, and recommending that applications be rewritten to use POSIX threads instead.

NOTES

The earliest incarnation of this mechanism was the *setjmp*(3)/*longjmp*(3) mechanism. Since that does not define the handling of the signal context, the next stage was the *sigsetjmp*(3)/*siglongjmp*(3) pair. The present mechanism gives much more control. On the other hand, there is no easy way to detect whether a return from **getcontext**() is from the first call, or via a **setcontext**() call. The user has to invent their own bookkeeping device, and a register variable won't do since registers are restored.

When a signal occurs, the current user context is saved and a new context is created by the kernel for the signal handler. Do not leave the handler using *longjmp*(3): it is undefined what would happen with contexts. Use *siglongjmp*(3) or **setcontext**() instead.

NAME

getcwd, getwd, get_current_dir_name − get current working directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

char *getcwd(char buf[.size], size_t size);
char *get_current_dir_name(void);

[[deprecated]] char *getwd(char buf[PATH_MAX]);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

get_current_dir_name():
_GNU_SOURCE

getwd():
Since glibc 2.12:
(_XOPEN_SOURCE >= 500) && ! (_POSIX_C_SOURCE >= 200809L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE
Before glibc 2.12:
_BSD_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

These functions return a null-terminated string containing an absolute pathname that is the current working directory of the calling process. The pathname is returned as the function result and via the argument *buf*, if present.

The **getcwd**() function copies an absolute pathname of the current working directory to the array pointed to by *buf*, which is of length *size*.

If the length of the absolute pathname of the current working directory, including the terminating null byte, exceeds *size* bytes, NULL is returned, and *errno* is set to **ERANGE**; an application should check for this error, and allocate a larger buffer if necessary.

As an extension to the POSIX.1-2001 standard, glibc's **getcwd**() allocates the buffer dynamically using *malloc*(3) if *buf* is NULL. In this case, the allocated buffer has the length *size* unless *size* is zero, when *buf* is allocated as big as necessary. The caller should *free*(3) the returned buffer.

get_current_dir_name() will *malloc*(3) an array big enough to hold the absolute pathname of the current working directory. If the environment variable **PWD** is set, and its value is correct, then that value will be returned. The caller should *free*(3) the returned buffer.

getwd() does not *malloc*(3) any memory. The *buf* argument should be a pointer to an array at least **PATH_MAX** bytes long. If the length of the absolute pathname of the current working directory, including the terminating null byte, exceeds **PATH_MAX** bytes, NULL is returned, and *errno* is set to **ENAMETOOLONG**. (Note that on some systems, **PATH_MAX** may not be a compile-time constant; furthermore, its value may depend on the filesystem, see *pathconf*(3).) For portability and security reasons, use of **getwd**() is deprecated.

RETURN VALUE

On success, these functions return a pointer to a string containing the pathname of the current working directory. In the case of **getcwd**() and **getwd**() this is the same value as *buf*.

On failure, these functions return NULL, and *errno* is set to indicate the error. The contents of the array pointed to by *buf* are undefined on error.

ERRORS

EACCES
Permission to read or search a component of the filename was denied.

EFAULT
buf points to a bad address.

EINVAL
The *size* argument is zero and *buf* is not a null pointer.

EINVAL
getwd(): *buf* is NULL.

ENAMETOOLONG
getwd(): The size of the null-terminated absolute pathname string exceeds **PATH_MAX** bytes.

ENOENT
The current working directory has been unlinked.

ENOMEM
Out of memory.

ERANGE
The *size* argument is less than the length of the absolute pathname of the working directory, including the terminating null byte. You need to allocate a bigger array and try again.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getcwd(), **getwd**()	Thread safety	MT-Safe
get_current_dir_name()	Thread safety	MT-Safe env

VERSIONS

POSIX.1-2001 leaves the behavior of **getcwd**() unspecified if *buf* is NULL.

POSIX.1-2001 does not define any errors for **getwd**().

VERSIONS

C library/kernel differences

On Linux, the kernel provides a **getcwd**() system call, which the functions described in this page will use if possible. The system call takes the same arguments as the library function of the same name, but is limited to returning at most **PATH_MAX** bytes. (Before Linux 3.12, the limit on the size of the returned pathname was the system page size. On many architectures, **PATH_MAX** and the system page size are both 4096 bytes, but a few architectures have a larger page size.) If the length of the pathname of the current working directory exceeds this limit, then the system call fails with the error **ENAMETOOLONG**. In this case, the library functions fall back to a (slower) alternative implementation that returns the full pathname.

Following a change in Linux 2.6.36, the pathname returned by the **getcwd**() system call will be prefixed with the string "(unreachable)" if the current directory is not below the root directory of the current process (e.g., because the process set a new filesystem root using *chroot*(2) without changing its current directory into the new root). Such behavior can also be caused by an unprivileged user by changing the current directory into another mount namespace. When dealing with pathname from untrusted sources, callers of the functions described in this page should consider checking whether the returned pathname starts with '/' or '(' to avoid misinterpreting an unreachable path as a relative pathname.

STANDARDS

getcwd()
POSIX.1-2008.

get_current_dir_name()
GNU.

getwd()
None.

HISTORY

getcwd()
POSIX.1-2001.

getwd()
POSIX.1-2001, but marked LEGACY. Removed in POSIX.1-2008. Use **getcwd**() instead.

Under Linux, these functions make use of the **getcwd**() system call (available since Linux 2.1.92). On older systems they would query */proc/self/cwd*. If both system call and proc filesystem are missing, a generic implementation is called. Only in that case can these calls fail under Linux with **EACCES**.

NOTES

These functions are often used to save the location of the current working directory for the purpose of returning to it later. Opening the current directory (".") and calling *fchdir*(2) to return is usually a faster and more reliable alternative when sufficiently many file descriptors are available, especially on platforms other than Linux.

BUGS

Since the Linux 2.6.36 change that added "(unreachable)" in the circumstances described above, the glibc implementation of **getcwd**() has failed to conform to POSIX and returned a relative pathname when the API contract requires an absolute pathname. With glibc 2.27 onwards this is corrected; calling **getcwd**() from such a pathname will now result in failure with **ENOENT**.

NAME

getdate, getdate_r − convert a date-plus-time string to broken-down time

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <time.h>

struct tm *getdate(const char *_string_);

extern int getdate_err;

int getdate_r(const char *restrict *string***, struct tm *restrict** *res***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getdate():
_XOPEN_SOURCE >= 500

getdate_r():
_GNU_SOURCE

DESCRIPTION

The function **getdate**() converts a string representation of a date and time, contained in the buffer pointed to by *string*, into a broken-down time. The broken-down time is stored in a *tm* structure, and a pointer to this structure is returned as the function result. This *tm* structure is allocated in static storage, and consequently it will be overwritten by further calls to **getdate**().

In contrast to *strptime*(3), (which has a *format* argument), **getdate**() uses the formats found in the file whose full pathname is given in the environment variable **DATEMSK**. The first line in the file that matches the given input string is used for the conversion.

The matching is done case insensitively. Superfluous whitespace, either in the pattern or in the string to be converted, is ignored.

The conversion specifications that a pattern can contain are those given for *strptime*(3). One more conversion specification is specified in POSIX.1-2001:

%Z Timezone name. This is not implemented in glibc.

When **%Z** is given, the structure containing the broken-down time is initialized with values corresponding to the current time in the given timezone. Otherwise, the structure is initialized to the broken-down time corresponding to the current local time (as by a call to *localtime*(3)).

When only the day of the week is given, the day is taken to be the first such day on or after today.

When only the month is given (and no year), the month is taken to be the first such month equal to or after the current month. If no day is given, it is the first day of the month.

When no hour, minute, and second are given, the current hour, minute, and second are taken.

If no date is given, but we know the hour, then that hour is taken to be the first such hour equal to or after the current hour.

getdate_r() is a GNU extension that provides a reentrant version of **getdate**(). Rather than using a global variable to report errors and a static buffer to return the broken down time, it returns errors via the function result value, and returns the resulting broken-down time in the caller-allocated buffer pointed to by the argument *res*.

RETURN VALUE

When successful, **getdate**() returns a pointer to a *struct tm*. Otherwise, it returns NULL and sets the global variable *getdate_err* to one of the error numbers shown below. Changes to *errno* are unspecified.

On success **getdate_r**() returns 0; on error it returns one of the error numbers shown below.

ERRORS

The following errors are returned via *getdate_err* (for *getdate*()) or as the function result (for *getdate_r*()):

1 The **DATEMSK** environment variable is not defined, or its value is an empty string.

2 The template file specified by **DATEMSK** cannot be opened for reading.

3 Failed to get file status information.

4 The template file is not a regular file.

5 An error was encountered while reading the template file.

6 Memory allocation failed (not enough memory available).

7 There is no line in the file that matches the input.

8 Invalid input specification.

ENVIRONMENT

DATEMSK
File containing format patterns.

TZ
LC_TIME
Variables used by *strptime*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getdate()	Thread safety	MT-Unsafe race:getdate env locale
getdate_r()	Thread safety	MT-Safe env locale

VERSIONS

The POSIX.1 specification for *strptime*(3) contains conversion specifications using the **%E** or **%O** modifier, while such specifications are not given for **getdate**(). In glibc, **getdate**() is implemented using *strptime*(3), so that precisely the same conversions are supported by both.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

The program below calls **getdate**() for each of its command-line arguments, and for each call displays the values in the fields of the returned *tm* structure. The following shell session demonstrates the operation of the program:

```
$ TFILE=$PWD/tfile
$ echo '%A' > $TFILE       # Full name of the day of the week
$ echo '%T' >> $TFILE      # Time (HH:MM:SS)
$ echo '%F' >> $TFILE      # ISO date (YYYY-MM-DD)
$ date
$ export DATEMSK=$TFILE
$ ./a.out Tuesday '2009-12-28' '12:22:33'
Sun Sep  7 06:03:36 CEST 2008
Call 1 ("Tuesday") succeeded:
    tm_sec   = 36
    tm_min   = 3
    tm_hour  = 6
    tm_mday  = 9
    tm_mon   = 8
    tm_year  = 108
    tm_wday  = 2
    tm_yday  = 252
    tm_isdst = 1
Call 2 ("2009-12-28") succeeded:
    tm_sec   = 36
    tm_min   = 3
```

```
            tm_hour  = 6
            tm_mday  = 28
            tm_mon   = 11
            tm_year  = 109
            tm_wday  = 1
            tm_yday  = 361
            tm_isdst = 0
        Call 3 ("12:22:33") succeeded:
            tm_sec   = 33
            tm_min   = 22
            tm_hour  = 12
            tm_mday  = 7
            tm_mon   = 8
            tm_year  = 108
            tm_wday  = 0
            tm_yday  = 250
            tm_isdst = 1
```

Program source

```
#define _GNU_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <time.h>

int
main(int argc, char *argv[])
{
    struct tm *tmp;

    for (size_t j = 1; j < argc; j++) {
        tmp = getdate(argv[j]);

        if (tmp == NULL) {
            printf("Call %zu failed; getdate_err = %d\n",
                   j, getdate_err);
            continue;
        }

        printf("Call %zu (\"%s\") succeeded:\n", j, argv[j]);
        printf("    tm_sec   = %d\n", tmp->tm_sec);
        printf("    tm_min   = %d\n", tmp->tm_min);
        printf("    tm_hour  = %d\n", tmp->tm_hour);
        printf("    tm_mday  = %d\n", tmp->tm_mday);
        printf("    tm_mon   = %d\n", tmp->tm_mon);
        printf("    tm_year  = %d\n", tmp->tm_year);
        printf("    tm_wday  = %d\n", tmp->tm_wday);
        printf("    tm_yday  = %d\n", tmp->tm_yday);
        printf("    tm_isdst = %d\n", tmp->tm_isdst);
    }

    exit(EXIT_SUCCESS);
}
```

NAME

getdirentries − get directory entries in a filesystem-independent format

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <dirent.h>

ssize_t getdirentries(int fd, char buf[restrict .nbytes], size_t nbytes,
                      off_t *restrict basep);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getdirentries():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

Read directory entries from the directory specified by *fd* into *buf*. At most *nbytes* are read. Reading starts at offset **basep*, and **basep* is updated with the new position after reading.

RETURN VALUE

getdirentries() returns the number of bytes read or zero when at the end of the directory. If an error occurs, −1 is returned, and *errno* is set to indicate the error.

ERRORS

See the Linux library source code for details.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getdirentries()	Thread safety	MT-Safe

STANDARDS

BSD.

NAME

getdtablesize − get file descriptor table size

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int getdtablesize(void);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getdtablesize():
Since glibc 2.20:
_DEFAULT_SOURCE || ! (_POSIX_C_SOURCE >= 200112L)
glibc 2.12 to glibc 2.19:
_BSD_SOURCE || ! (_POSIX_C_SOURCE >= 200112L)
Before glibc 2.12:
_BSD_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

getdtablesize() returns the maximum number of files a process can have open, one more than the largest possible value for a file descriptor.

RETURN VALUE

The current limit on the number of open files per process.

ERRORS

On Linux, **getdtablesize**() can return any of the errors described for *getrlimit*(2); see NOTES below.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getdtablesize()	Thread safety	MT-Safe

VERSIONS

The glibc version of **getdtablesize**() calls *getrlimit*(2) and returns the current **RLIMIT_NOFILE** limit, or **OPEN_MAX** when that fails.

Portable applications should employ *sysconf(_SC_OPEN_MAX)* instead of this call.

STANDARDS

None.

HISTORY

SVr4, 4.4BSD (first appeared in 4.2BSD).

SEE ALSO

close(2), *dup*(2), *getrlimit*(2), *open*(2)

NAME

getentropy − fill a buffer with random bytes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int getentropy(void *buffer***[.**_length_**], size_t** *length***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getentropy():
_DEFAULT_SOURCE

DESCRIPTION

The **getentropy**() function writes *length* bytes of high-quality random data to the buffer starting at the location pointed to by *buffer*. The maximum permitted value for the *length* argument is 256.

A successful call to **getentropy**() always provides the requested number of bytes of entropy.

RETURN VALUE

On success, this function returns zero. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EFAULT
Part or all of the buffer specified by *buffer* and *length* is not in valid addressable memory.

EIO *length* is greater than 256.

EIO An unspecified error occurred while trying to overwrite *buffer* with random data.

ENOSYS
This kernel version does not implement the *getrandom*(2) system call required to implement this function.

STANDARDS

None.

HISTORY

glibc 2.25. OpenBSD.

NOTES

The **getentropy**() function is implemented using *getrandom*(2).

Whereas the glibc wrapper makes *getrandom*(2) a cancelation point, **getentropy**() is not a cancelation point.

getentropy() is also declared in **<sys/random.h>**. (No feature test macro need be defined to obtain the declaration from that header file.)

A call to **getentropy**() may block if the system has just booted and the kernel has not yet collected enough randomness to initialize the entropy pool. In this case, **getentropy**() will keep blocking even if a signal is handled, and will return only once the entropy pool has been initialized.

SEE ALSO

getrandom(2), *urandom*(4), *random*(7)

NAME

getenv, secure_getenv − get an environment variable

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

char *getenv(const char *name);
char *secure_getenv(const char *name);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

secure_getenv():
_GNU_SOURCE

DESCRIPTION

The **getenv**() function searches the environment list to find the environment variable *name*, and returns a pointer to the corresponding *value* string.

The GNU-specific **secure_getenv**() function is just like **getenv**() except that it returns NULL in cases where "secure execution" is required. Secure execution is required if one of the following conditions was true when the program run by the calling process was loaded:

- the process's effective user ID did not match its real user ID or the process's effective group ID did not match its real group ID (typically this is the result of executing a set-user-ID or set-group-ID program);
- the effective capability bit was set on the executable file; or
- the process has a nonempty permitted capability set.

Secure execution may also be required if triggered by some Linux security modules.

The **secure_getenv**() function is intended for use in general-purpose libraries to avoid vulnerabilities that could occur if set-user-ID or set-group-ID programs accidentally trusted the environment.

RETURN VALUE

The **getenv**() function returns a pointer to the value in the environment, or NULL if there is no match.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getenv(), **secure_getenv**()	Thread safety	MT-Safe env

STANDARDS

getenv()
C11, POSIX.1-2008.

secure_getenv()
GNU.

HISTORY

getenv()
POSIX.1-2001, C89, C99, SVr4, 4.3BSD.

secure_getenv()
glibc 2.17.

NOTES

The strings in the environment list are of the form *name=value*.

As typically implemented, **getenv**() returns a pointer to a string within the environment list. The caller must take care not to modify this string, since that would change the environment of the process.

The implementation of **getenv**() is not required to be reentrant. The string pointed to by the return value of **getenv**() may be statically allocated, and can be modified by a subsequent call to **getenv**(), *putenv*(3), *setenv*(3), or *unsetenv*(3).

The "secure execution" mode of **secure_getenv**() is controlled by the **AT_SECURE** flag contained in the auxiliary vector passed from the kernel to user space.

NAME

getfsent, getfsspec, getfsfile, setfsent, endfsent − handle fstab entries

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <fstab.h>

int setfsent(void);
struct fstab *getfsent(void);
void endfsent(void);

struct fstab *getfsfile(const char *_mount_point_);
struct fstab *getfsspec(const char *_special_file_);

DESCRIPTION

These functions read from the file */etc/fstab*. The *struct fstab* is defined by:

```
struct fstab {
    char       *fs_spec;       /* block device name */
    char       *fs_file;       /* mount point */
    char       *fs_vfstype;    /* filesystem type */
    char       *fs_mntops;     /* mount options */
    const char *fs_type;       /* rw/rq/ro/sw/xx option */
    int         fs_freq;       /* dump frequency, in days */
    int         fs_passno;     /* pass number on parallel dump */
};
```

Here the field *fs_type* contains (on a *BSD system) one of the five strings "rw", "rq", "ro", "sw", "xx" (read-write, read-write with quota, read-only, swap, ignore).

The function **setfsent**() opens the file when required and positions it at the first line.

The function **getfsent**() parses the next line from the file. (After opening it when required.)

The function **endfsent**() closes the file when required.

The function **getfsspec**() searches the file from the start and returns the first entry found for which the *fs_spec* field matches the *special_file* argument.

The function **getfsfile**() searches the file from the start and returns the first entry found for which the *fs_file* field matches the *mount_point* argument.

RETURN VALUE

Upon success, the functions **getfsent**(), **getfsfile**(), and **getfsspec**() return a pointer to a *struct fstab*, while **setfsent**() returns 1. Upon failure or end-of-file, these functions return NULL and 0, respectively.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
endfsent(), **setfsent**()	Thread safety	MT-Unsafe race:fsent
getfsent(), **getfsspec**(), **getfsfile**()	Thread safety	MT-Unsafe race:fsent locale

VERSIONS

Several operating systems have these functions, for example, *BSD, SunOS, Digital UNIX, AIX (which also has a *getfstype*())HP-UX has functions of the same names, that however use a *struct checklist* instead of a *struct fstab*, and calls these functions obsolete, superseded by *getmntent*(3).

STANDARDS

None.

HISTORY

The **getfsent**() function appeared in 4.0BSD; the other four functions appeared in 4.3BSD.

NOTES

These functions are not thread-safe.

Since Linux allows mounting a block special device in several places, and since several devices can

have the same mount point, where the last device with a given mount point is the interesting one, while **getfsfile**() and **getfsspec**() only return the first occurrence, these two functions are not suitable for use under Linux.

SEE ALSO

getmntent(3), *fstab*(5)

NAME

getgrent, setgrent, endgrent − get group file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <grp.h>

struct group *getgrent(void);

void setgrent(void);
void endgrent(void);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

setgrent():
_XOPEN_SOURCE >= 500
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

getgrent(), **endgrent**():
Since glibc 2.22:
_XOPEN_SOURCE >= 500 || _DEFAULT_SOURCE
glibc 2.21 and earlier
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getgrent**() function returns a pointer to a structure containing the broken-out fields of a record in the group database (e.g., the local group file */etc/group*, NIS, and LDAP). The first time **getgrent**() is called, it returns the first entry; thereafter, it returns successive entries.

The **setgrent**() function rewinds to the beginning of the group database, to allow repeated scans.

The **endgrent**() function is used to close the group database after all processing has been performed.

The *group* structure is defined in <*grp.h*> as follows:

```
struct group {
    char   *gr_name;        /* group name */
    char   *gr_passwd;      /* group password */
    gid_t   gr_gid;         /* group ID */
    char  **gr_mem;         /* NULL-terminated array of pointers
                               to names of group members */
};
```

For more information about the fields of this structure, see *group*(5).

RETURN VALUE

The **getgrent**() function returns a pointer to a *group* structure, or NULL if there are no more entries or an error occurs.

Upon error, *errno* may be set. If one wants to check *errno* after the call, it should be set to zero before the call.

The return value may point to a static area, and may be overwritten by subsequent calls to **getgrent**(), *getgrgid*(3), or *getgrnam*(3). (Do not pass the returned pointer to *free*(3).)

ERRORS

EAGAIN
The service was temporarily unavailable; try again later. For NSS backends in glibc this indicates a temporary error talking to the backend. The error may correct itself, retrying later is suggested.

EINTR
A signal was caught; see *signal*(7).

EIO I/O error.

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOENT
A necessary input file cannot be found. For NSS backends in glibc this indicates the backend is not correctly configured.

ENOMEM
Insufficient memory to allocate *group* structure.

ERANGE
Insufficient buffer space supplied.

FILES

/etc/group
local group database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getgrent()	Thread safety	MT-Unsafe race:grent race:grentbuf locale
setgrent(), **endgrent**()	Thread safety	MT-Unsafe race:grent locale

In the above table, *grent* in *race:grent* signifies that if any of the functions **setgrent**(), **getgrent**(), or **endgrent**() are used in parallel in different threads of a program, then data races could occur.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

SEE ALSO

fgetgrent(3), *getgrent_r*(3), *getgrgid*(3), *getgrnam*(3), *getgrouplist*(3), *putgrent*(3), *group*(5)

NAME

getgrent_r, fgetgrent_r − get group file entry reentrantly

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <grp.h>

int getgrent_r(struct group *restrict gbuf,
               char buf[restrict .buflen], size_t buflen,
               struct group **restrict gbufp);
int fgetgrent_r(FILE *restrict stream, struct group *restrict gbuf,
               char buf[restrict .buflen], size_t buflen,
               struct group **restrict gbufp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getgrent_r():
_GNU_SOURCE

fgetgrent_r():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

The functions **getgrent_r**() and **fgetgrent_r**() are the reentrant versions of *getgrent*(3) and *fgetgrent*(3). The former reads the next group entry from the stream initialized by *setgrent*(3). The latter reads the next group entry from *stream*.

The *group* structure is defined in <*grp.h*> as follows:

```
struct group {
    char   *gr_name;        /* group name */
    char   *gr_passwd;      /* group password */
    gid_t   gr_gid;         /* group ID */
    char  **gr_mem;         /* NULL-terminated array of pointers
                               to names of group members */
};
```

For more information about the fields of this structure, see *group*(5).

The nonreentrant functions return a pointer to static storage, where this static storage contains further pointers to group name, password, and members. The reentrant functions described here return all of that in caller-provided buffers. First of all there is the buffer *gbuf* that can hold a *struct group*. And next the buffer *buf* of size *buflen* that can hold additional strings. The result of these functions, the *struct group* read from the stream, is stored in the provided buffer **gbuf*, and a pointer to this *struct group* is returned in **gbufp*.

RETURN VALUE

On success, these functions return 0 and **gbufp* is a pointer to the *struct group*. On error, these functions return an error value and **gbufp* is NULL.

ERRORS

ENOENT
No more entries.

ERANGE
Insufficient buffer space supplied. Try again with larger buffer.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getgrent_r()	Thread safety	MT-Unsafe race:grent locale
fgetgrent_r()	Thread safety	MT-Safe

In the above table, *grent* in *race:grent* signifies that if any of the functions *setgrent*(3), *getgrent*(3), *endgrent*(3), or **getgrent_r**() are used in parallel in different threads of a program, then data races could occur.

VERSIONS

Other systems use the prototype

```
struct group *getgrent_r(struct group *grp, char *buf,
                         int buflen);
```

or, better,

```
int getgrent_r(struct group *grp, char *buf, int buflen,
               FILE **gr_fp);
```

STANDARDS

GNU.

HISTORY

These functions are done in a style resembling the POSIX version of functions like *getpwnam_r*(3).

NOTES

The function **getgrent_r**() is not really reentrant since it shares the reading position in the stream with all other threads.

EXAMPLES

```
#define _GNU_SOURCE
#include <grp.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#define BUFLEN 4096

int
main(void)
{
    struct group grp;
    struct group *grpp;
    char buf[BUFLEN];
    int i;

    setgrent();
    while (1) {
        i = getgrent_r(&grp, buf, sizeof(buf), &grpp);
        if (i)
            break;
        printf("%s (%jd):", grpp->gr_name, (intmax_t) grpp->gr_gid);
        for (size_t j = 0; ; j++) {
            if (grpp->gr_mem[j] == NULL)
                break;
            printf(" %s", grpp->gr_mem[j]);
        }
        printf("\n");
    }
    endgrent();
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

fgetgrent(3), *getgrent*(3), *getgrgid*(3), *getgrnam*(3), *putgrent*(3), *group*(5)

NAME

getgrnam, getgrnam_r, getgrgid, getgrgid_r − get group file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <grp.h>

struct group *getgrnam(const char *name);
struct group *getgrgid(gid_t gid);

int getgrnam_r(const char *restrict name, struct group *restrict grp,
        char buf[restrict .buflen], size_t buflen,
        struct group **restrict result);
int getgrgid_r(gid_t gid, struct group *restrict grp,
        char buf[restrict .buflen], size_t buflen,
        struct group **restrict result);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getgrnam_r(), **getgrgid_r**():
_POSIX_C_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getgrnam**() function returns a pointer to a structure containing the broken-out fields of the record in the group database (e.g., the local group file */etc/group*, NIS, and LDAP) that matches the group name *name*.

The **getgrgid**() function returns a pointer to a structure containing the broken-out fields of the record in the group database that matches the group ID *gid*.

The *group* structure is defined in <*grp.h*> as follows:

```
struct group {
    char   *gr_name;        /* group name */
    char   *gr_passwd;      /* group password */
    gid_t   gr_gid;         /* group ID */
    char  **gr_mem;         /* NULL-terminated array of pointers
                               to names of group members */
};
```

For more information about the fields of this structure, see *group*(5).

The **getgrnam_r**() and **getgrgid_r**() functions obtain the same information as **getgrnam**() and **getgrgid**(), but store the retrieved *group* structure in the space pointed to by *grp*. The string fields pointed to by the members of the *group* structure are stored in the buffer *buf* of size *buflen*. A pointer to the result (in case of success) or NULL (in case no entry was found or an error occurred) is stored in **result*.

The call

```
sysconf(_SC_GETGR_R_SIZE_MAX)
```

returns either −1, without changing *errno*, or an initial suggested size for *buf*. (If this size is too small, the call fails with **ERANGE**, in which case the caller can retry with a larger buffer.)

RETURN VALUE

The **getgrnam**() and **getgrgid**() functions return a pointer to a *group* structure, or NULL if the matching entry is not found or an error occurs. If an error occurs, *errno* is set to indicate the error. If one wants to check *errno* after the call, it should be set to zero before the call.

The return value may point to a static area, and may be overwritten by subsequent calls to *getgrent*(3), **getgrgid**(), or **getgrnam**(). (Do not pass the returned pointer to *free*(3).)

On success, **getgrnam_r**() and **getgrgid_r**() return zero, and set **result* to *grp*. If no matching group record was found, these functions return 0 and store NULL in **result*. In case of error, an error number is returned, and NULL is stored in **result*.

ERRORS

0 or **ENOENT** or **ESRCH** or **EBADF** or **EPERM** or ...
The given *name* or *gid* was not found.

EINTR
A signal was caught; see *signal*(7).

EIO I/O error.

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOMEM
Insufficient memory to allocate *group* structure.

ERANGE
Insufficient buffer space supplied.

FILES

/etc/group
local group database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getgrnam()	Thread safety	MT-Unsafe race:grnam locale
getgrgid()	Thread safety	MT-Unsafe race:grgid locale
getgrnam_r(), **getgrgid_r**()	Thread safety	MT-Safe locale

VERSIONS

The formulation given above under "RETURN VALUE" is from POSIX.1. It does not call "not found" an error, hence does not specify what value *errno* might have in this situation. But that makes it impossible to recognize errors. One might argue that according to POSIX *errno* should be left unchanged if an entry is not found. Experiments on various UNIX-like systems show that lots of different values occur in this situation: 0, ENOENT, EBADF, ESRCH, EWOULDBLOCK, EPERM, and probably others.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

SEE ALSO

endgrent(3), *fgetgrent*(3), *getgrent*(3), *getpwnam*(3), *setgrent*(3), *group*(5)

NAME

getgrouplist − get list of groups to which a user belongs

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <grp.h>

int getgrouplist(const char *user, gid_t group,
                 gid_t *groups, int *ngroups);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getgrouplist():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The **getgrouplist**() function scans the group database (see *group*(5)) to obtain the list of groups that *user* belongs to. Up to **ngroups* of these groups are returned in the array *groups*.

If it was not among the groups defined for *user* in the group database, then *group* is included in the list of groups returned by **getgrouplist**(); typically this argument is specified as the group ID from the password record for *user*.

The *ngroups* argument is a value-result argument: on return it always contains the number of groups found for *user*, including *group*; this value may be greater than the number of groups stored in *groups*.

RETURN VALUE

If the number of groups of which *user* is a member is less than or equal to **ngroups*, then the value **ngroups* is returned.

If the user is a member of more than **ngroups* groups, then **getgrouplist**() returns −1. In this case, the value returned in **ngroups* can be used to resize the buffer passed to a further call to **getgrouplist**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getgrouplist()	Thread safety	MT-Safe locale

STANDARDS

None.

HISTORY

glibc 2.2.4.

BUGS

Before glibc 2.3.3, the implementation of this function contains a buffer-overrun bug: it returns the complete list of groups for *user* in the array *groups*, even when the number of groups exceeds **ngroups*.

EXAMPLES

The program below displays the group list for the user named in its first command-line argument. The second command-line argument specifies the *ngroups* value to be supplied to **getgrouplist**(). The following shell session shows examples of the use of this program:

```
$ ./a.out cecilia 0
getgrouplist() returned -1; ngroups = 3
$ ./a.out cecilia 3
ngroups = 3
16 (dialout)
33 (video)
100 (users)
```

Program source

```
#include <grp.h>
#include <pwd.h>
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
{
    int            ngroups;
    gid_t          *groups;
    struct group   *gr;
    struct passwd  *pw;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <user> <ngroups>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    ngroups = atoi(argv[2]);

    groups = malloc(sizeof(*groups) * ngroups);
    if (groups == NULL) {
        perror("malloc");
        exit(EXIT_FAILURE);
    }

    /* Fetch passwd structure (contains first group ID for user). */

    pw = getpwnam(argv[1]);
    if (pw == NULL) {
        perror("getpwnam");
        exit(EXIT_SUCCESS);
    }

    /* Retrieve group list. */

    if (getgrouplist(argv[1], pw->pw_gid, groups, &ngroups) == -1) {
        fprintf(stderr, "getgrouplist() returned -1; ngroups = %d\n",
                ngroups);
        exit(EXIT_FAILURE);
    }

    /* Display list of retrieved groups, along with group names. */

    fprintf(stderr, "ngroups = %d\n", ngroups);
    for (int j = 0; j < ngroups; j++) {
        printf("%d", groups[j]);
        gr = getgrgid(groups[j]);
        if (gr != NULL)
            printf(" (%s)", gr->gr_name);
        printf("\n");
    }

    exit(EXIT_SUCCESS);
}
```

glibc 2.12 to glibc 2.19:
_BSD_SOURCE || _SVID_SOURCE || _POSIX_C_SOURCE < 200809L
Before glibc 2.12:
none

DESCRIPTION

The **gethostbyname***(), **gethostbyaddr***(), **herror**(), and **hstrerror**() functions are obsolete. Applications should use *getaddrinfo*(3), *getnameinfo*(3), and *gai_strerror*(3) instead.

The **sethostent**() function specifies, if *stayopen* is true (1), that a connected TCP socket should be used for the name server queries and that the connection should remain open during successive queries. Otherwise, name server queries will use UDP datagrams.

The **endhostent**() function ends the use of a TCP connection for name server queries.

The **gethostbyname**() function returns a structure of type *hostent* for the given host *name*. Here *name* is either a hostname or an IPv4 address in standard dot notation (as for *inet_addr*(3)). If *name* is an IPv4 address, no lookup is performed and **gethostbyname**() simply copies *name* into the *h_name* field and its *struct in_addr* equivalent into the *h_addr_list[0]* field of the returned *hostent* structure. If *name* doesn't end in a dot and the environment variable **HOSTALIASES** is set, the alias file pointed to by **HOSTALIASES** will first be searched for *name* (see *hostname*(7) for the file format). The current domain and its parents are searched unless *name* ends in a dot.

The **gethostbyaddr**() function returns a structure of type *hostent* for the given host address *addr* of length *len* and address type *type*. Valid address types are **AF_INET** and **AF_INET6** (defined in <*sys/socket.h*>). The host address argument is a pointer to a struct of a type depending on the address type, for example a *struct in_addr* * (probably obtained via a call to *inet_addr*(3)) for address type **AF_INET**.

The (obsolete) **herror**() function prints the error message associated with the current value of *h_errno* on *stderr*.

The (obsolete) **hstrerror**() function takes an error number (typically *h_errno*) and returns the corresponding message string.

The domain name queries carried out by **gethostbyname**() and **gethostbyaddr**() rely on the Name Service Switch (**nsswitch.conf**(5)) configured sources or a local name server (**named**(8)). The default action is to query the Name Service Switch (**nsswitch.conf**(5)) configured sources, failing that, a local name server (**named**(8)).

Historical

The *nsswitch.conf*(5) file is the modern way of controlling the order of host lookups.

In glibc 2.4 and earlier, the *order* keyword was used to control the order of host lookups as defined in */etc/host.conf* (**host.conf**(5)).

The *hostent* structure is defined in <*netdb.h*> as follows:

```
struct hostent {
    char  *h_name;            /* official name of host */
    char **h_aliases;         /* alias list */
    int    h_addrtype;        /* host address type */
    int    h_length;          /* length of address */
    char **h_addr_list;       /* list of addresses */
}
#define h_addr h_addr_list[0] /* for backward compatibility */
```

The members of the *hostent* structure are:

h_name
The official name of the host.

h_aliases
An array of alternative names for the host, terminated by a null pointer.

h_addrtype
The type of address; always **AF_INET** or **AF_INET6** at present.

h_length
The length of the address in bytes.

h_addr_list
An array of pointers to network addresses for the host (in network byte order), terminated by a null pointer.

h_addr The first address in *h_addr_list* for backward compatibility.

RETURN VALUE

The **gethostbyname**() and **gethostbyaddr**() functions return the *hostent* structure or a null pointer if an error occurs. On error, the *h_errno* variable holds an error number. When non-NULL, the return value may point at static data, see the notes below.

ERRORS

The variable *h_errno* can have the following values:

HOST_NOT_FOUND
The specified host is unknown.

NO_DATA
The requested name is valid but does not have an IP address. Another type of request to the name server for this domain may return an answer. The constant **NO_ADDRESS** is a synonym for **NO_DATA**.

NO_RECOVERY
A nonrecoverable name server error occurred.

TRY_AGAIN
A temporary error occurred on an authoritative name server. Try again later.

FILES

/etc/host.conf
resolver configuration file

/etc/hosts
host database file

/etc/nsswitch.conf
name service switch configuration

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gethostbyname()	Thread safety	MT-Unsafe race:hostbyname env locale
gethostbyaddr()	Thread safety	MT-Unsafe race:hostbyaddr env locale
sethostent(), **endhostent**(), **gethostent_r**()	Thread safety	MT-Unsafe race:hostent env locale
herror(), **hstrerror**()	Thread safety	MT-Safe
gethostent()	Thread safety	MT-Unsafe race:hostent race:hostentbuf env locale
gethostbyname2()	Thread safety	MT-Unsafe race:hostbyname2 env locale
gethostbyaddr_r(), **gethostbyname_r**(), **gethostbyname2_r**()	Thread safety	MT-Safe env locale

In the above table, *hostent* in *race:hostent* signifies that if any of the functions **sethostent**(), **gethostent**(), **gethostent_r**(), or **endhostent**() are used in parallel in different threads of a program, then data races could occur.

STANDARDS

sethostent()
endhostent()
gethostent()
POSIX.1-2008.

gethostent_r()
GNU.

Others: None.

HISTORY

sethostent()
endhostent()
gethostent()
POSIX.1-2001.

gethostbyname()
gethostbyaddr()
h_errno
Marked obsolescent in POSIX.1-2001. Removed in POSIX.1-2008, recommending the use of *getaddrinfo*(3) and *getnameinfo*(3) instead.

NOTES

The functions **gethostbyname**() and **gethostbyaddr**() may return pointers to static data, which may be overwritten by later calls. Copying the *struct hostent* does not suffice, since it contains pointers; a deep copy is required.

In the original BSD implementation the *len* argument of **gethostbyname**() was an *int*. The SUSv2 standard is buggy and declares the *len* argument of **gethostbyaddr**() to be of type *size_t*. (That is wrong, because it has to be *int*, and *size_t* is not. POSIX.1-2001 makes it *socklen_t*, which is OK.) See also *accept*(2).

The BSD prototype for **gethostbyaddr**() uses *const char* * for the first argument.

System V/POSIX extension

POSIX requires the **gethostent**() call, which should return the next entry in the host data base. When using DNS/BIND this does not make much sense, but it may be reasonable if the host data base is a file that can be read line by line. On many systems, a routine of this name reads from the file */etc/hosts*. It may be available only when the library was built without DNS support. The glibc version will ignore ipv6 entries. This function is not reentrant, and glibc adds a reentrant version **gethostent_r**().

GNU extensions

glibc2 also has a **gethostbyname2**() that works like **gethostbyname**(), but permits to specify the address family to which the address must belong.

glibc2 also has reentrant versions **gethostent_r**(), **gethostbyaddr_r**(), **gethostbyname_r**(), and **gethostbyname2_r**(). The caller supplies a *hostent* structure *ret* which will be filled in on success, and a temporary work buffer *buf* of size *buflen*. After the call, *result* will point to the result on success. In case of an error or if no entry is found *result* will be NULL. The functions return 0 on success and a nonzero error number on failure. In addition to the errors returned by the nonreentrant versions of these functions, if *buf* is too small, the functions will return **ERANGE**, and the call should be retried with a larger buffer. The global variable *h_errno* is not modified, but the address of a variable in which to store error numbers is passed in *h_errnop*.

BUGS

gethostbyname() does not recognize components of a dotted IPv4 address string that are expressed in hexadecimal.

NAME

gethostid, sethostid − get or set the unique identifier of the current host

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

long gethostid(void);
int sethostid(long hostid);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

gethostid():
Since glibc 2.20:
_DEFAULT_SOURCE || _XOPEN_SOURCE >= 500
Up to and including glibc 2.19:
_BSD_SOURCE || _XOPEN_SOURCE >= 500

sethostid():
Since glibc 2.21:
_DEFAULT_SOURCE
In glibc 2.19 and 2.20:
_DEFAULT_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)
Up to and including glibc 2.19:
_BSD_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)

DESCRIPTION

gethostid() and **sethostid**() respectively get or set a unique 32-bit identifier for the current machine. The 32-bit identifier was intended to be unique among all UNIX systems in existence. This normally resembles the Internet address for the local machine, as returned by *gethostbyname*(3), and thus usually never needs to be set.

The **sethostid**() call is restricted to the superuser.

RETURN VALUE

gethostid() returns the 32-bit identifier for the current host as set by **sethostid**().

On success, **sethostid**() returns 0; on error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

sethostid() can fail with the following errors:

EACCES
The caller did not have permission to write to the file used to store the host ID.

EPERM
The calling process's effective user or group ID is not the same as its corresponding real ID.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gethostid()	Thread safety	MT-Safe hostid env locale
sethostid()	Thread safety	MT-Unsafe const:hostid

VERSIONS

In the glibc implementation, the *hostid* is stored in the file */etc/hostid*. (Before glibc 2.2, the file */var/adm/hostid* was used.)

In the glibc implementation, if **gethostid**() cannot open the file containing the host ID, then it obtains the hostname using *gethostname*(2), passes that hostname to *gethostbyname_r*(3) in order to obtain the host's IPv4 address, and returns a value obtained by bit-twiddling the IPv4 address. (This value may not be unique.)

STANDARDS

gethostid()
POSIX.1-2008.

sethostid()
None.

HISTORY

4.2BSD; dropped in 4.4BSD. SVr4 and POSIX.1-2001 include **gethostid**() but not **sethostid**().

BUGS

It is impossible to ensure that the identifier is globally unique.

SEE ALSO

hostid(1), *gethostbyname*(3)

NAME

getifaddrs, freeifaddrs − get interface addresses

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/types.h>
#include <ifaddrs.h>

int getifaddrs(struct ifaddrs *****ifap*);**
void freeifaddrs(struct ifaddrs ****ifa*);**

DESCRIPTION

The **getifaddrs**() function creates a linked list of structures describing the network interfaces of the local system, and stores the address of the first item of the list in **ifap*. The list consists of *ifaddrs* structures, defined as follows:

```
struct ifaddrs {
    struct ifaddrs  *ifa_next;    /* Next item in list */
    char            *ifa_name;    /* Name of interface */
    unsigned int     ifa_flags;   /* Flags from SIOCGIFFLAGS */
    struct sockaddr *ifa_addr;    /* Address of interface */
    struct sockaddr *ifa_netmask; /* Netmask of interface */
    union {
        struct sockaddr *ifu_broadaddr;
                         /* Broadcast address of interface */
        struct sockaddr *ifu_dstaddr;
                         /* Point-to-point destination address */
    } ifa_ifu;
#define              ifa_broadaddr ifa_ifu.ifu_broadaddr
#define              ifa_dstaddr   ifa_ifu.ifu_dstaddr
    void            *ifa_data;    /* Address-specific data */
};
```

The *ifa_next* field contains a pointer to the next structure on the list, or NULL if this is the last item of the list.

The *ifa_name* points to the null-terminated interface name.

The *ifa_flags* field contains the interface flags, as returned by the **SIOCGIFFLAGS** *ioctl*(2) operation (see *netdevice*(7) for a list of these flags).

The *ifa_addr* field points to a structure containing the interface address. (The *sa_family* subfield should be consulted to determine the format of the address structure.) This field may contain a null pointer.

The *ifa_netmask* field points to a structure containing the netmask associated with *ifa_addr*, if applicable for the address family. This field may contain a null pointer.

Depending on whether the bit **IFF_BROADCAST** or **IFF_POINTOPOINT** is set in *ifa_flags* (only one can be set at a time), either *ifa_broadaddr* will contain the broadcast address associated with *ifa_addr* (if applicable for the address family) or *ifa_dstaddr* will contain the destination address of the point-to-point interface.

The *ifa_data* field points to a buffer containing address-family-specific data; this field may be NULL if there is no such data for this interface.

The data returned by **getifaddrs**() is dynamically allocated and should be freed using **freeifaddrs**() when no longer needed.

RETURN VALUE

On success, **getifaddrs**() returns zero; on error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

getifaddrs() may fail and set *errno* for any of the errors specified for *socket*(2), *bind*(2), *getsockname*(2), *recvmsg*(2), *sendto*(2), *malloc*(3), or *realloc*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getifaddrs(), **freeifaddrs**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

This function first appeared in BSDi and is present on the BSD systems, but with slightly different semantics documented—returning one entry per interface, not per address. This means *ifa_addr* and other fields can actually be NULL if the interface has no address, and no link-level address is returned if the interface has an IP address assigned. Also, the way of choosing either *ifa_broadaddr* or *ifa_dstaddr* differs on various systems.

getifaddrs() first appeared in glibc 2.3, but before glibc 2.3.3, the implementation supported only IPv4 addresses; IPv6 support was added in glibc 2.3.3. Support of address families other than IPv4 is available only on kernels that support netlink.

NOTES

The addresses returned on Linux will usually be the IPv4 and IPv6 addresses assigned to the interface, but also one **AF_PACKET** address per interface containing lower-level details about the interface and its physical layer. In this case, the *ifa_data* field may contain a pointer to a *struct rtnl_link_stats*, defined in <*linux/if_link.h*> (in Linux 2.4 and earlier, *struct net_device_stats*, defined in <*linux/netdevice.h*>), which contains various interface attributes and statistics.

EXAMPLES

The program below demonstrates the use of **getifaddrs**(), **freeifaddrs**(), and *getnameinfo*(3). Here is what we see when running this program on one system:

```
$ ./a.out
lo       AF_PACKET (17)
                tx_packets =        524; rx_packets =        524
                tx_bytes   =      38788; rx_bytes   =      38788
wlp3s0   AF_PACKET (17)
                tx_packets =     108391; rx_packets =     130245
                tx_bytes   =   30420659; rx_bytes   =   94230014
em1      AF_PACKET (17)
                tx_packets =          0; rx_packets =          0
                tx_bytes   =          0; rx_bytes   =          0
lo       AF_INET (2)
                address: <127.0.0.1>
wlp3s0   AF_INET (2)
                address: <192.168.235.137>
lo       AF_INET6 (10)
                address: <::1>
wlp3s0   AF_INET6 (10)
                address: <fe80::7ee9:d3ff:fef5:1a91%wlp3s0>
```

Program source

```
#define _GNU_SOURCE     /* To get defns of NI_MAXSERV and NI_MAXHOST */
#include <arpa/inet.h>
#include <sys/socket.h>
#include <netdb.h>
#include <ifaddrs.h>

NAME

getipnodebyname, getipnodebyaddr, freehostent − get network hostnames and addresses

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <sys/socket.h>
#include <netdb.h>

[[deprecated]] struct hostent *getipnodebyname(const char *name, int af,
                        int flags, int *error_num);
[[deprecated]] struct hostent *getipnodebyaddr(const void addr[.len],
                        size_t len, int af,
                        int *error_num);
[[deprecated]] void freehostent(struct hostent *ip);
```

DESCRIPTION

These functions are deprecated (and unavailable in glibc). Use *getaddrinfo*(3) and *getnameinfo*(3) instead.

The **getipnodebyname**() and **getipnodebyaddr**() functions return the names and addresses of a network host. These functions return a pointer to the following structure:

```
struct hostent {
    char  *h_name;
    char **h_aliases;
    int    h_addrtype;
    int    h_length;
    char **h_addr_list;
};
```

These functions replace the *gethostbyname*(3) and *gethostbyaddr*(3) functions, which could access only the IPv4 network address family. The **getipnodebyname**() and **getipnodebyaddr**() functions can access multiple network address families.

Unlike the **gethostby** functions, these functions return pointers to dynamically allocated memory. The **freehostent**() function is used to release the dynamically allocated memory after the caller no longer needs the *hostent* structure.

getipnodebyname() arguments

The **getipnodebyname**() function looks up network addresses for the host specified by the *name* argument. The *af* argument specifies one of the following values:

AF_INET
: The *name* argument points to a dotted-quad IPv4 address or a name of an IPv4 network host.

AF_INET6
: The *name* argument points to a hexadecimal IPv6 address or a name of an IPv6 network host.

The *flags* argument specifies additional options. More than one option can be specified by bitwise ORing them together. *flags* should be set to 0 if no options are desired.

AI_V4MAPPED
: This flag is used with **AF_INET6** to request a query for IPv4 addresses instead of IPv6 addresses; the IPv4 addresses will be mapped to IPv6 addresses.

AI_ALL
: This flag is used with **AI_V4MAPPED** to request a query for both IPv4 and IPv6 addresses. Any IPv4 address found will be mapped to an IPv6 address.

AI_ADDRCONFIG
: This flag is used with **AF_INET6** to further request that queries for IPv6 addresses should not be made unless the system has at least one IPv6 address assigned to a network interface, and that queries for IPv4 addresses should not be made unless the system has at least one IPv4 address assigned to a network interface. This flag may be used by itself or with the **AI_V4MAPPED** flag.

AI_DEFAULT
This flag is equivalent to **(AI_ADDRCONFIG | AI_V4MAPPED)**.

getipnodebyaddr() arguments
The **getipnodebyaddr**() function looks up the name of the host whose network address is specified by the *addr* argument. The *af* argument specifies one of the following values:

AF_INET
The *addr* argument points to a *struct in_addr* and *len* must be set to *sizeof(struct in_addr)*.

AF_INET6
The *addr* argument points to a *struct in6_addr* and *len* must be set to *sizeof(struct in6_addr)*.

RETURN VALUE
NULL is returned if an error occurred, and *error_num* will contain an error code from the following list:

HOST_NOT_FOUND
The hostname or network address was not found.

NO_ADDRESS
The domain name server recognized the network address or name, but no answer was returned. This can happen if the network host has only IPv4 addresses and a request has been made for IPv6 information only, or vice versa.

NO_RECOVERY
The domain name server returned a permanent failure response.

TRY_AGAIN
The domain name server returned a temporary failure response. You might have better luck next time.

A successful query returns a pointer to a *hostent* structure that contains the following fields:

h_name
This is the official name of this network host.

h_aliases
This is an array of pointers to unofficial aliases for the same host. The array is terminated by a null pointer.

h_addrtype
This is a copy of the *af* argument to **getipnodebyname**() or **getipnodebyaddr**(). *h_addrtype* will always be **AF_INET** if the *af* argument was **AF_INET**. *h_addrtype* will always be **AF_INET6** if the *af* argument was **AF_INET6**.

h_length
This field will be set to *sizeof(struct in_addr)* if *h_addrtype* is **AF_INET**, and to *sizeof(struct in6_addr)* if *h_addrtype* is **AF_INET6**.

h_addr_list
This is an array of one or more pointers to network address structures for the network host. The array is terminated by a null pointer.

STANDARDS
None.

HISTORY
RFC 2553.

Present in glibc 2.1.91-95, but removed again. Several UNIX-like systems support them, but all call them deprecated.

getaddrinfo(3), *getnameinfo*(3), *inet_ntop*(3), *inet_pton*(3)

NAME

getline, getdelim − delimited string input

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

ssize_t getline(char **restrict lineptr, size_t *restrict n,
                FILE *restrict stream);
ssize_t getdelim(char **restrict lineptr, size_t *restrict n,
                 int delim, FILE *restrict stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getline(), **getdelim**():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

getline() reads an entire line from *stream*, storing the address of the buffer containing the text into **lineptr*. The buffer is null-terminated and includes the newline character, if one was found.

If **lineptr* is set to NULL before the call, then **getline**() will allocate a buffer for storing the line. This buffer should be freed by the user program even if **getline**() failed.

Alternatively, before calling **getline**(), **lineptr* can contain a pointer to a *malloc*(3)-allocated buffer **n* bytes in size. If the buffer is not large enough to hold the line, **getline**() resizes it with *realloc*(3), updating **lineptr* and **n* as necessary.

In either case, on a successful call, **lineptr* and **n* will be updated to reflect the buffer address and allocated size respectively.

getdelim() works like **getline**(), except that a line delimiter other than newline can be specified as the *delimiter* argument. As with **getline**(), a delimiter character is not added if one was not present in the input before end of file was reached.

RETURN VALUE

On success, **getline**() and **getdelim**() return the number of characters read, including the delimiter character, but not including the terminating null byte ('\0'). This value can be used to handle embedded null bytes in the line read.

Both functions return −1 on failure to read a line (including end-of-file condition). In the event of a failure, *errno* is set to indicate the error.

If **lineptr* was set to NULL before the call, then the buffer should be freed by the user program even on failure.

ERRORS

EINVAL
Bad arguments (*n* or *lineptr* is NULL, or *stream* is not valid).

ENOMEM
Allocation or reallocation of the line buffer failed.

ATTRIBUTES

NAME

getloadavg − get system load averages

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int getloadavg(double *loadavg[]***, int** *nelem***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getloadavg():
Since glibc 2.19:
_DEFAULT_SOURCE
In glibc up to and including 2.19:
_BSD_SOURCE

DESCRIPTION

The **getloadavg**() function returns the number of processes in the system run queue averaged over various periods of time. Up to *nelem* samples are retrieved and assigned to successive elements of *loadavg[]*. The system imposes a maximum of 3 samples, representing averages over the last 1, 5, and 15 minutes, respectively.

RETURN VALUE

If the load average was unobtainable, −1 is returned; otherwise, the number of samples actually retrieved is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getloadavg()	Thread safety	MT-Safe

STANDARDS

BSD.

HISTORY

4.3BSD-Reno, Solaris. glibc 2.2.

SEE ALSO

NAME

getlogin, getlogin_r, cuserid − get username

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

char *getlogin(void);
int getlogin_r(char *buf* **[.***bufsize***], size_t** *bufsize***);**

#include <stdio.h>

char *cuserid(char * *string***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getlogin_r():
_POSIX_C_SOURCE >= 199506L

cuserid():
Since glibc 2.24:
(_XOPEN_SOURCE && ! (_POSIX_C_SOURCE >= 200112L)
|| _GNU_SOURCE
Up to and including glibc 2.23:
_XOPEN_SOURCE

DESCRIPTION

getlogin() returns a pointer to a string containing the name of the user logged in on the controlling terminal of the process, or a null pointer if this information cannot be determined. The string is statically allocated and might be overwritten on subsequent calls to this function or to **cuserid**().

getlogin_r() returns this same username in the array *buf* of size *bufsize*.

cuserid() returns a pointer to a string containing a username associated with the effective user ID of the process. If *string* is not a null pointer, it should be an array that can hold at least **L_cuserid** characters; the string is returned in this array. Otherwise, a pointer to a string in a static area is returned. This string is statically allocated and might be overwritten on subsequent calls to this function or to **getlogin**().

The macro **L_cuserid** is an integer constant that indicates how long an array you might need to store a username. **L_cuserid** is declared in <*stdio.h*>.

These functions let your program identify positively the user who is running (**cuserid**()) or the user who logged in this session (**getlogin**()). (These can differ when set-user-ID programs are involved.)

For most purposes, it is more useful to use the environment variable **LOGNAME** to find out who the user is. This is more flexible precisely because the user can set **LOGNAME** arbitrarily.

RETURN VALUE

getlogin() returns a pointer to the username when successful, and NULL on failure, with *errno* set to indicate the error. **getlogin_r**() returns 0 when successful, and nonzero on failure.

ERRORS

POSIX specifies:

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENXIO
The calling process has no controlling terminal.

ERANGE
(getlogin_r) The length of the username, including the terminating null byte ('\0'), is larger than *bufsize*.

Linux/glibc also has:

ENOENT
There was no corresponding entry in the utmp-file.

ENOMEM
Insufficient memory to allocate passwd structure.

ENOTTY
Standard input didn't refer to a terminal. (See BUGS.)

FILES

/etc/passwd
password database file

/var/run/utmp
(traditionally */etc/utmp*; some libc versions used */var/adm/utmp*)

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getlogin()	Thread safety	MT-Unsafe race:getlogin race:utent sig:ALRM timer locale
getlogin_r()	Thread safety	MT-Unsafe race:utent sig:ALRM timer locale
cuserid()	Thread safety	MT-Unsafe race:cuserid/!string locale

In the above table, *utent* in *race:utent* signifies that if any of the functions *setutent*(3), *getutent*(3), or *endutent*(3) are used in parallel in different threads of a program, then data races could occur. **getlogin**() and **getlogin_r**() call those functions, so we use race:utent to remind users.

VERSIONS

OpenBSD has **getlogin**() and **setlogin**(), and a username associated with a session, even if it has no controlling terminal.

STANDARDS

getlogin()
getlogin_r()
POSIX.1-2008.

cuserid()
None.

STANDARDS

getlogin()
getlogin_r():
POSIX.1-2001. OpenBSD.

cuserid()
System V, POSIX.1-1988. Removed in POSIX.1-1990. SUSv2. Removed in POSIX.1-2001.

System V has a **cuserid**() function which uses the real user ID rather than the effective user ID.

BUGS

Unfortunately, it is often rather easy to fool **getlogin**(). Sometimes it does not work at all, because some program messed up the utmp file. Often, it gives only the first 8 characters of the login name. The user currently logged in on the controlling terminal of our program need not be the user who started it. Avoid **getlogin**() for security-related purposes.

Note that glibc does not follow the POSIX specification and uses *stdin* instead of */dev/tty*. A bug. (Other recent systems, like SunOS 5.8 and HP-UX 11.11 and FreeBSD 4.8 all return the login name also when *stdin* is redirected.)

Nobody knows precisely what **cuserid**() does; avoid it in portable programs. Or avoid it altogether: use *getpwuid(geteuid())* instead, if that is what you meant. **Do not use cuserid**().

SEE ALSO

logname(1), *geteuid*(2), *getuid*(2), *utmp*(5)

NAME

getmntent, setmntent, addmntent, endmntent, hasmntopt, getmntent_r − get filesystem descriptor file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <mntent.h>

FILE *setmntent(const char *filename, const char *type);

struct mntent *getmntent(FILE *stream);

int addmntent(FILE *restrict stream,
              const struct mntent *restrict mnt);

int endmntent(FILE *streamp);

char *hasmntopt(const struct mntent *mnt, const char *opt);

/* GNU extension */
#include <mntent.h>

struct mntent *getmntent_r(FILE *restrict streamp,
              struct mntent *restrict mntbuf,
              char buf[restrict .buflen], int buflen);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getmntent_r():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These routines are used to access the filesystem description file */etc/fstab* and the mounted filesystem description file */etc/mtab*.

The **setmntent**() function opens the filesystem description file *filename* and returns a file pointer which can be used by **getmntent**(). The argument *type* is the type of access required and can take the same values as the *mode* argument of *fopen*(3). The returned stream should be closed using **endmntent**() rather than *fclose*(3).

The **getmntent**() function reads the next line of the filesystem description file from *stream* and returns a pointer to a structure containing the broken out fields from a line in the file. The pointer points to a static area of memory which is overwritten by subsequent calls to **getmntent**().

The **addmntent**() function adds the *mntent* structure *mnt* to the end of the open *stream*.

The **endmntent**() function closes the *stream* associated with the filesystem description file.

The **hasmntopt**() function scans the *mnt_opts* field (see below) of the *mntent* structure *mnt* for a substring that matches *opt*. See <*mntent.h*> and *mount*(8) for valid mount options.

The reentrant **getmntent_r**() function is similar to **getmntent**(), but stores the *mntent* structure in the provided **mntbuf*, and stores the strings pointed to by the entries in that structure in the provided array *buf* of size *buflen*.

The *mntent* structure is defined in <*mntent.h*> as follows:

```
struct mntent {
    char *mnt_fsname;   /* name of mounted filesystem */
    char *mnt_dir;      /* filesystem path prefix */
    char *mnt_type;     /* mount type (see mntent.h) */
    char *mnt_opts;     /* mount options (see mntent.h) */
    int   mnt_freq;     /* dump frequency in days */
    int   mnt_passno;   /* pass number on parallel fsck */
};
```

Since fields in the mtab and fstab files are separated by whitespace, octal escapes are used to represent the characters space (\040), tab (\011), newline (\012), and backslash (\\) in those files when they occur in one of the four strings in a *mntent* structure. The routines **addmntent**() and **getmntent**() will convert from string representation to escaped representation and back. When converting from escaped representation, the sequence \134 is also converted to a backslash.

RETURN VALUE

The **getmntent**() and **getmntent_r**() functions return a pointer to the *mntent* structure or NULL on failure.

The **addmntent**() function returns 0 on success and 1 on failure.

The **endmntent**() function always returns 1.

The **hasmntopt**() function returns the address of the substring if a match is found and NULL otherwise.

FILES

/etc/fstab
: filesystem description file

/etc/mtab
: mounted filesystem description file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setmntent(), **endmntent**(), **hasmntopt**()	Thread safety	MT-Safe
getmntent()	Thread safety	MT-Unsafe race:mntentbuf locale
addmntent()	Thread safety	MT-Safe race:stream locale
getmntent_r()	Thread safety	MT-Safe locale

STANDARDS

None.

HISTORY

The nonreentrant functions are from SunOS 4.1.3. A routine **getmntent_r**() was introduced in HP-UX 10, but it returns an *int*. The prototype shown above is glibc-only.

System V also has a **getmntent**() function but the calling sequence differs, and the returned structure is different. Under System V */etc/mnttab* is used. 4.4BSD and Digital UNIX have a routine **getmntinfo**(), a wrapper around the system call **getfsstat**().

SEE ALSO

fopen(3), *fstab*(5), *mount*(8)

NAME

getnameinfo − address-to-name translation in protocol-independent manner

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/socket.h>
#include <netdb.h>

int getnameinfo(const struct sockaddr *restrict addr, socklen_t addrlen,
                char host[_Nullable restrict .hostlen],
                socklen_t hostlen,
                char serv[_Nullable restrict .servlen],
                socklen_t servlen,
                int  flags);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getnameinfo():
Since glibc 2.22:
_POSIX_C_SOURCE >= 200112L
glibc 2.21 and earlier:
_POSIX_C_SOURCE

DESCRIPTION

The **getnameinfo**() function is the inverse of *getaddrinfo*(3): it converts a socket address to a corresponding host and service, in a protocol-independent manner. It combines the functionality of *gethostbyaddr*(3) and *getservbyport*(3), but unlike those functions, **getnameinfo**() is reentrant and allows programs to eliminate IPv4-versus-IPv6 dependencies.

The *addr* argument is a pointer to a generic socket address structure (of type *sockaddr_in* or *sockaddr_in6*) of size *addrlen* that holds the input IP address and port number. The arguments *host* and *serv* are pointers to caller-allocated buffers (of size *hostlen* and *servlen* respectively) into which **getnameinfo**() places null-terminated strings containing the host and service names respectively.

The caller can specify that no hostname (or no service name) is required by providing a NULL *host* (or *serv*) argument or a zero *hostlen* (or *servlen*) argument. However, at least one of hostname or service name must be requested.

The *flags* argument modifies the behavior of **getnameinfo**() as follows:

NI_NAMEREQD
If set, then an error is returned if the hostname cannot be determined.

NI_DGRAM
If set, then the service is datagram (UDP) based rather than stream (TCP) based. This is required for the few ports (512–514) that have different services for UDP and TCP.

NI_NOFQDN
If set, return only the hostname part of the fully qualified domain name for local hosts.

NI_NUMERICHOST
If set, then the numeric form of the hostname is returned. (When not set, this will still happen in case the node's name cannot be determined.)

NI_NUMERICSERV
If set, then the numeric form of the service address is returned. (When not set, this will still happen in case the service's name cannot be determined.)

Extensions to getnameinfo() for Internationalized Domain Names

Starting with glibc 2.3.4, **getnameinfo**() has been extended to selectively allow hostnames to be transparently converted to and from the Internationalized Domain Name (IDN) format (see RFC 3490, *Internationalizing Domain Names in Applications (IDNA)*). Three new flags are defined:

NI_IDN
If this flag is used, then the name found in the lookup process is converted from IDN format to the locale's encoding if necessary. ASCII-only names are not affected by the conversion,

which makes this flag usable in existing programs and environments.

NI_IDN_ALLOW_UNASSIGNED
NI_IDN_USE_STD3_ASCII_RULES
Setting these flags will enable the IDNA_ALLOW_UNASSIGNED (allow unassigned Unicode code points) and IDNA_USE_STD3_ASCII_RULES (check output to make sure it is a STD3 conforming hostname) flags respectively to be used in the IDNA handling.

RETURN VALUE

On success, 0 is returned, and node and service names, if requested, are filled with null-terminated strings, possibly truncated to fit the specified buffer lengths. On error, one of the following nonzero error codes is returned:

EAI_AGAIN
The name could not be resolved at this time. Try again later.

EAI_BADFLAGS
The *flags* argument has an invalid value.

EAI_FAIL
A nonrecoverable error occurred.

EAI_FAMILY
The address family was not recognized, or the address length was invalid for the specified family.

EAI_MEMORY
Out of memory.

EAI_NONAME
The name does not resolve for the supplied arguments. **NI_NAMEREQD** is set and the host's name cannot be located, or neither hostname nor service name were requested.

EAI_OVERFLOW
The buffer pointed to by *host* or *serv* was too small.

EAI_SYSTEM
A system error occurred. The error code can be found in *errno*.

The *gai_strerror*(3) function translates these error codes to a human readable string, suitable for error reporting.

FILES

/etc/hosts
/etc/nsswitch.conf
/etc/resolv.conf

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getnameinfo()	Thread safety	MT-Safe env locale

STANDARDS

POSIX.1-2008. RFC 2553.

HISTORY

glibc 2.1. POSIX.1-2001.

Before glibc 2.2, the *hostlen* and *servlen* arguments were typed as *size_t*.

NOTES

In order to assist the programmer in choosing reasonable sizes for the supplied buffers, <*netdb.h*> defines the constants

```
#define NI_MAXHOST      1025
#define NI_MAXSERV      32
```

Since glibc 2.8, these definitions are exposed only if suitable feature test macros are defined, namely: **_GNU_SOURCE**, **_DEFAULT_SOURCE** (since glibc 2.19), or (in glibc versions up to and including 2.19) **_BSD_SOURCE** or **_SVID_SOURCE**.

The former is the constant **MAXDNAME** in recent versions of BIND's <*arpa/nameser.h*> header file. The latter is a guess based on the services listed in the current Assigned Numbers RFC.

EXAMPLES

The following code tries to get the numeric hostname and service name, for a given socket address. Note that there is no hardcoded reference to a particular address family.

```
struct sockaddr *addr;     /* input */
socklen_t addrlen;         /* input */
char hbuf[NI_MAXHOST], sbuf[NI_MAXSERV];

if (getnameinfo(addr, addrlen, hbuf, sizeof(hbuf), sbuf,
            sizeof(sbuf), NI_NUMERICHOST | NI_NUMERICSERV) == 0)
    printf("host=%s, serv=%s\n", hbuf, sbuf);
```

The following version checks if the socket address has a reverse address mapping.

```
struct sockaddr *addr;     /* input */
socklen_t addrlen;         /* input */
char hbuf[NI_MAXHOST];

if (getnameinfo(addr, addrlen, hbuf, sizeof(hbuf),
            NULL, 0, NI_NAMEREQD))
    printf("could not resolve hostname");
else
    printf("host=%s\n", hbuf);
```

An example program using **getnameinfo**() can be found in *getaddrinfo*(3).

NAME

getnetent, getnetbyname, getnetbyaddr, setnetent, endnetent − get network entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <netdb.h>

struct netent *getnetent(void);

struct netent *getnetbyname(const char *_name_);
struct netent *getnetbyaddr(uint32_t _net_, int _type_);

void setnetent(int _stayopen_);
void endnetent(void);

DESCRIPTION

The **getnetent**() function reads the next entry from the networks database and returns a *netent* structure containing the broken-out fields from the entry. A connection is opened to the database if necessary.

The **getnetbyname**() function returns a *netent* structure for the entry from the database that matches the network *name*.

The **getnetbyaddr**() function returns a *netent* structure for the entry from the database that matches the network number *net* of type *type*. The *net* argument must be in host byte order.

The **setnetent**() function opens a connection to the database, and sets the next entry to the first entry. If *stayopen* is nonzero, then the connection to the database will not be closed between calls to one of the **getnet***() functions.

The **endnetent**() function closes the connection to the database.

The *netent* structure is defined in <*netdb.h*> as follows:

```
struct netent {
    char      *n_name;     /* official network name */
    char     **n_aliases;  /* alias list */
    int        n_addrtype; /* net address type */
    uint32_t   n_net;      /* network number */
}
```

The members of the *netent* structure are:

n_name
: The official name of the network.

n_aliases
: A NULL-terminated list of alternative names for the network.

n_addrtype
: The type of the network number; always **AF_INET**.

n_net
: The network number in host byte order.

RETURN VALUE

The **getnetent**(), **getnetbyname**(), and **getnetbyaddr**() functions return a pointer to a statically allocated *netent* structure, or a null pointer if an error occurs or the end of the file is reached.

FILES

/etc/networks
: networks database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getnetent()	Thread safety	MT-Unsafe race:netent race:netentbuf env locale
getnetbyname()	Thread safety	MT-Unsafe race:netbyname env locale
getnetbyaddr()	Thread safety	MT-Unsafe race:netbyaddr locale
setnetent(), **endnetent**()	Thread safety	MT-Unsafe race:netent env locale

In the above table, *netent* in *race:netent* signifies that if any of the functions **setnetent**(), **getnetent**(), or **endnetent**() are used in parallel in different threads of a program, then data races could occur.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.3BSD.

Before glibc 2.2, the *net* argument of **getnetbyaddr**() was of type *long*.

SEE ALSO

getnetent_r(3), *getprotoent*(3), *getservent*(3)
RFC 1101

NAME

getnetent_r, getnetbyname_r, getnetbyaddr_r − get network entry (reentrant)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

int getnetent_r(struct netent *restrict result_buf,
                char buf[restrict .buflen], size_t buflen,
                struct netent **restrict result,
                int *restrict h_errnop);
int getnetbyname_r(const char *restrict name,
                struct netent *restrict result_buf,
                char buf[restrict .buflen], size_t buflen,
                struct netent **restrict result,
                int *restrict h_errnop);
int getnetbyaddr_r(uint32_t net, int type,
                struct netent *restrict result_buf,
                char buf[restrict .buflen], size_t buflen,
                struct netent **restrict result,
                int *restrict h_errnop);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getnetent_r(), **getnetbyname_r**(), **getnetbyaddr_r**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getnetent_r**(), **getnetbyname_r**(), and **getnetbyaddr_r**() functions are the reentrant equivalents of, respectively, *getnetent*(3), *getnetbyname*(3), and *getnetbynumber*(3)They differ in the way that the *netent* structure is returned, and in the function calling signature and return value. This manual page describes just the differences from the nonreentrant functions.

Instead of returning a pointer to a statically allocated *netent* structure as the function result, these functions copy the structure into the location pointed to by *result_buf*.

The *buf* array is used to store the string fields pointed to by the returned *netent* structure. (The nonreentrant functions allocate these strings in static storage.) The size of this array is specified in *buflen*. If *buf* is too small, the call fails with the error **ERANGE**, and the caller must try again with a larger buffer. (A buffer of length 1024 bytes should be sufficient for most applications.)

If the function call successfully obtains a network record, then **result* is set pointing to *result_buf*; otherwise, **result* is set to NULL.

The buffer pointed to by *h_errnop* is used to return the value that would be stored in the global variable *h_errno* by the nonreentrant versions of these functions.

RETURN VALUE

On success, these functions return 0. On error, they return one of the positive error numbers listed in ERRORS.

On error, record not found (**getnetbyname_r**(), *getnetbyaddr_r*()), or end of input (**getnetent_r**()) *result* is set to NULL.

ERRORS

ENOENT
(**getnetent_r**()) No more records in database.

ERANGE
buf is too small. Try again with a larger buffer (and increased *buflen*).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getnetent_r(), **getnetbyname_r**(), **getnetbyaddr_r**()	Thread safety	MT-Safe locale

VERSIONS

Functions with similar names exist on some other systems, though typically with different calling signatures.

STANDARDS

GNU.

getnetent(3), *networks*(5)

NAME

getopt, getopt_long, getopt_long_only, optarg, optind, opterr, optopt − Parse command-line options

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

int getopt(int argc, char *argv[],
           const char *optstring);

extern char *optarg;
extern int optind, opterr, optopt;

#include <getopt.h>

int getopt_long(int argc, char *argv[],
           const char *optstring,
           const struct option *longopts, int *longindex);
int getopt_long_only(int argc, char *argv[],
           const char *optstring,
           const struct option *longopts, int *longindex);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getopt():
_POSIX_C_SOURCE >= 2 || _XOPEN_SOURCE

getopt_long(), **getopt_long_only**():
_GNU_SOURCE

DESCRIPTION

The **getopt**() function parses the command-line arguments. Its arguments *argc* and *argv* are the argument count and array as passed to the *main*() function on program invocation. An element of *argv* that starts with '−' (and is not exactly "−" or "−−") is an option element. The characters of this element (aside from the initial '−') are option characters. If **getopt**() is called repeatedly, it returns successively each of the option characters from each of the option elements.

The variable *optind* is the index of the next element to be processed in *argv*. The system initializes this value to 1. The caller can reset it to 1 to restart scanning of the same *argv*, or when scanning a new argument vector.

If **getopt**() finds another option character, it returns that character, updating the external variable *optind* and a static variable *nextchar* so that the next call to **getopt**() can resume the scan with the following option character or *argv*-element.

If there are no more option characters, **getopt**() returns −1. Then *optind* is the index in *argv* of the first *argv*-element that is not an option.

optstring is a string containing the legitimate option characters. A legitimate option character is any visible one byte *ascii*(7) character (for which *isgraph*(3) would return nonzero) that is not '−', ':', or ';'. If such a character is followed by a colon, the option requires an argument, so **getopt**() places a pointer to the following text in the same *argv*-element, or the text of the following *argv*-element, in *optarg*. Two colons mean an option takes an optional arg; if there is text in the current *argv*-element (i.e., in the same word as the option name itself, for example, "−oarg"), then it is returned in *optarg*, otherwise *optarg* is set to zero. This is a GNU extension. If *optstring* contains **W** followed by a semicolon, then **−W foo** is treated as the long option **--foo**. (The **−W** option is reserved by POSIX.2 for implementation extensions.) This behavior is a GNU extension, not available with libraries before glibc 2.

By default, **getopt**() permutes the contents of *argv* as it scans, so that eventually all the nonoptions are at the end. Two other scanning modes are also implemented. If the first character of *optstring* is '+' or the environment variable **POSIXLY_CORRECT** is set, then option processing stops as soon as a nonoption argument is encountered. If '+' is not the first character of *optstring*, it is treated as a normal option. If **POSIXLY_CORRECT** behaviour is required in this case *optstring* will contain two '+' symbols. If the first character of *optstring* is '−', then each nonoption *argv*-element is handled as if it were the argument of an option with character code 1. (This is used by programs that were written to expect options and other *argv*-elements in any order and that care about the ordering of the two.) The

special argument "−−" forces an end of option-scanning regardless of the scanning mode.

While processing the option list, **getopt**() can detect two kinds of errors: (1) an option character that was not specified in *optstring* and (2) a missing option argument (i.e., an option at the end of the command line without an expected argument). Such errors are handled and reported as follows:

- By default, **getopt**() prints an error message on standard error, places the erroneous option character in *optopt*, and returns '?' as the function result.
- If the caller has set the global variable *opterr* to zero, then **getopt**() does not print an error message. The caller can determine that there was an error by testing whether the function return value is '?'. (By default, *opterr* has a nonzero value.)
- If the first character (following any optional '+' or '−' described above) of *optstring* is a colon (':'), then **getopt**() likewise does not print an error message. In addition, it returns ':' instead of '?' to indicate a missing option argument. This allows the caller to distinguish the two different types of errors.

getopt_long() and getopt_long_only()

The **getopt_long**() function works like **getopt**() except that it also accepts long options, started with two dashes. (If the program accepts only long options, then *optstring* should be specified as an empty string (""), not NULL.) Long option names may be abbreviated if the abbreviation is unique or is an exact match for some defined option. A long option may take a parameter, of the form **−−arg=param** or **--arg param**.

longopts is a pointer to the first element of an array of *struct option* declared in <*getopt.h*> as

```
struct option {
    const char *name;
    int         has_arg;
    int        *flag;
    int         val;
};
```

The meanings of the different fields are:

name is the name of the long option.

has_arg
: is: **no_argument** (or 0) if the option does not take an argument; **required_argument** (or 1) if the option requires an argument; or **optional_argument** (or 2) if the option takes an optional argument.

flag specifies how results are returned for a long option. If *flag* is NULL, then **getopt_long**() returns *val*. (For example, the calling program may set *val* to the equivalent short option character.) Otherwise, **getopt_long**() returns 0, and *flag* points to a variable which is set to *val* if the option is found, but left unchanged if the option is not found.

val is the value to return, or to load into the variable pointed to by *flag*.

The last element of the array has to be filled with zeros.

If *longindex* is not NULL, it points to a variable which is set to the index of the long option relative to *longopts*.

getopt_long_only() is like **getopt_long**(), but '−' as well as "−−" can indicate a long option. If an option that starts with '−' (not "−−") doesn't match a long option, but does match a short option, it is parsed as a short option instead.

RETURN VALUE

If an option was successfully found, then **getopt**() returns the option character. If all command-line options have been parsed, then **getopt**() returns −1. If **getopt**() encounters an option character that was not in *optstring*, then '?' is returned. If **getopt**() encounters an option with a missing argument, then the return value depends on the first character in *optstring*: if it is ':', then ':' is returned; otherwise '?' is returned.

getopt_long() and **getopt_long_only**() also return the option character when a short option is recognized. For a long option, they return *val* if *flag* is NULL, and 0 otherwise. Error and −1 returns are the same as for **getopt**(), plus '?' for an ambiguous match or an extraneous parameter.

ENVIRONMENT

POSIXLY_CORRECT
If this is set, then option processing stops as soon as a nonoption argument is encountered.

_<PID>_GNU_nonoption_argv_flags_
This variable was used by *bash*(1) 2.0 to communicate to glibc which arguments are the results of wildcard expansion and so should not be considered as options. This behavior was removed in *bash*(1) 2.01, but the support remains in glibc.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getopt(), **getopt_long**(), **getopt_long_only**()	Thread safety	MT-Unsafe race:getopt env

VERSIONS

POSIX specifies that the *argv* array argument should be *const*, but these functions permute its elements unless the environment variable **POSIXLY_CORRECT** is set. *const* is used in the actual prototype to be compatible with other systems; however, this page doesn't show the qualifier, to avoid confusing readers.

STANDARDS

getopt()
POSIX.1-2008.

getopt_long()
getopt_long_only()
GNU.

The use of '+' and '−' in *optstring* is a GNU extension.

HISTORY

getopt()
POSIX.1-2001, and POSIX.2.

On some older implementations, **getopt**() was declared in <*stdio.h*>. SUSv1 permitted the declaration to appear in either <*unistd.h*> or <*stdio.h*>. POSIX.1-1996 marked the use of <*stdio.h*> for this purpose as LEGACY. POSIX.1-2001 does not require the declaration to appear in <*stdio.h*>.

NOTES

A program that scans multiple argument vectors, or rescans the same vector more than once, and wants to make use of GNU extensions such as '+' and '−' at the start of *optstring*, or changes the value of **POSIXLY_CORRECT** between scans, must reinitialize **getopt**() by resetting *optind* to 0, rather than the traditional value of 1. (Resetting to 0 forces the invocation of an internal initialization routine that rechecks **POSIXLY_CORRECT** and checks for GNU extensions in *optstring*.)

Command-line arguments are parsed in strict order meaning that an option requiring an argument will consume the next argument, regardless of whether that argument is the correctly specified option argument or simply the next option (in the scenario the user mis-specifies the command line). For example, if *optstring* is specified as "1n:" and the user specifies the command line arguments incorrectly as *prog −n −1*, the *−n* option will be given the **optarg** value "−1", and the *−1* option will be considered to have not been specified.

EXAMPLES

getopt()

The following trivial example program uses **getopt**() to handle two program options: *−n*, with no associated value; and *−t val*, which expects an associated value.

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    int flags, opt;
```

```
        int nsecs, tfnd;

        nsecs = 0;
        tfnd = 0;
        flags = 0;
        while ((opt = getopt(argc, argv, "nt:")) != -1) {
            switch (opt) {
            case 'n':
                flags = 1;
                break;
            case 't':
                nsecs = atoi(optarg);
                tfnd = 1;
                break;
            default: /* '?' */
                fprintf(stderr, "Usage: %s [-t nsecs] [-n] name\n",
                        argv[0]);
                exit(EXIT_FAILURE);
            }
        }

        printf("flags=%d; tfnd=%d; nsecs=%d; optind=%d\n",
               flags, tfnd, nsecs, optind);

        if (optind >= argc) {
            fprintf(stderr, "Expected argument after options\n");
            exit(EXIT_FAILURE);
        }

        printf("name argument = %s\n", argv[optind]);

        /* Other code omitted */

        exit(EXIT_SUCCESS);
    }
```

getopt_long()

The following example program illustrates the use of **getopt_long**() with most of its features.

```
    #include <getopt.h>
    #include <stdio.h>     /* for printf */
    #include <stdlib.h>    /* for exit */

    int
    main(int argc, char *argv[])
    {
        int c;
        int digit_optind = 0;

        while (1) {
            int this_option_optind = optind ? optind : 1;
            int option_index = 0;
            static struct option long_options[] = {
                {"add",     required_argument, 0,  0 },
                {"append",  no_argument,       0,  0 },
                {"delete",  required_argument, 0,  0 },
                {"verbose", no_argument,       0,  0 },
                {"create",  required_argument, 0, 'c'},
                {"file",    required_argument, 0,  0 },
                {0,         0,                 0,  0 }
```

```
            };

            c = getopt_long(argc, argv, "abc:d:012",
                            long_options, &option_index);
            if (c == -1)
                break;

            switch (c) {
            case 0:
                printf("option %s", long_options[option_index].name);
                if (optarg)
                    printf(" with arg %s", optarg);
                printf("\n");
                break;

            case '0':
            case '1':
            case '2':
                if (digit_optind != 0 && digit_optind != this_option_optind)
                  printf("digits occur in two different argv-elements.\n");
                digit_optind = this_option_optind;
                printf("option %c\n", c);
                break;

            case 'a':
                printf("option a\n");
                break;

            case 'b':
                printf("option b\n");
                break;

            case 'c':
                printf("option c with value '%s'\n", optarg);
                break;

            case 'd':
                printf("option d with value '%s'\n", optarg);
                break;

            case '?':
                break;

            default:
                printf("?? getopt returned character code 0%o ??\n", c);
            }
        }

        if (optind < argc) {
            printf("non-option ARGV-elements: ");
            while (optind < argc)
                printf("%s ", argv[optind++]);
            printf("\n");
        }

        exit(EXIT_SUCCESS);
    }
```

NAME

getpass − get a password

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

[[deprecated]] char *getpass(const char * *prompt***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getpass():
Since glibc 2.2.2:
_XOPEN_SOURCE && ! (_POSIX_C_SOURCE >= 200112L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE
Before glibc 2.2.2:
none

DESCRIPTION

This function is obsolete. Do not use it. See NOTES. If you want to read input without terminal echoing enabled, see the description of the *ECHO* flag in *termios*(3).

The **getpass**() function opens */dev/tty* (the controlling terminal of the process), outputs the string *prompt*, turns off echoing, reads one line (the "password"), restores the terminal state and closes */dev/tty* again.

RETURN VALUE

The function **getpass**() returns a pointer to a static buffer containing (the first **PASS_MAX** bytes of) the password without the trailing newline, terminated by a null byte ('\0'). This buffer may be overwritten by a following call. On error, the terminal state is restored, *errno* is set to indicate the error, and NULL is returned.

ERRORS

ENXIO
The process does not have a controlling terminal.

FILES

/dev/tty

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getpass()	Thread safety	MT-Unsafe term

STANDARDS

None.

HISTORY

Version 7 AT&T UNIX. Present in SUSv2, but marked LEGACY. Removed in POSIX.1-2001.

NOTES

You should use instead *readpassphrase*(3bsd), provided by *libbsd*.

In the GNU C library implementation, if */dev/tty* cannot be opened, the prompt is written to *stderr* and the password is read from *stdin*. There is no limit on the length of the password. Line editing is not disabled.

According to SUSv2, the value of **PASS_MAX** must be defined in <*limits.h*> in case it is smaller than 8, and can in any case be obtained using *sysconf(_SC_PASS_MAX)*. However, POSIX.2 withdraws the constants **PASS_MAX** and **_SC_PASS_MAX**, and the function **getpass**(). The glibc version accepts **_SC_PASS_MAX** and returns **BUFSIZ** (e.g., 8192).

BUGS

The calling process should zero the password as soon as possible to avoid leaving the cleartext password visible in the process's address space.

crypt(3)

NAME

getprotoent, getprotobyname, getprotobynumber, setprotoent, endprotoent − get protocol entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <netdb.h>

struct protoent *getprotoent(void);

struct protoent *getprotobyname(const char *_name_);
struct protoent *getprotobynumber(int *proto***);**

void setprotoent(int *stayopen***);**
void endprotoent(void);

DESCRIPTION

The **getprotoent**() function reads the next entry from the protocols database (see *protocols*(5)) and returns a *protoent* structure containing the broken-out fields from the entry. A connection is opened to the database if necessary.

The **getprotobyname**() function returns a *protoent* structure for the entry from the database that matches the protocol name *name*. A connection is opened to the database if necessary.

The **getprotobynumber**() function returns a *protoent* structure for the entry from the database that matches the protocol number *number*. A connection is opened to the database if necessary.

The **setprotoent**() function opens a connection to the database, and sets the next entry to the first entry. If *stayopen* is nonzero, then the connection to the database will not be closed between calls to one of the **getproto***() functions.

The **endprotoent**() function closes the connection to the database.

The *protoent* structure is defined in <*netdb.h*> as follows:

```
struct protoent {
    char  *p_name;       /* official protocol name */
    char **p_aliases;    /* alias list */
    int    p_proto;      /* protocol number */
}
```

The members of the *protoent* structure are:

p_name
: The official name of the protocol.

p_aliases
: A NULL-terminated list of alternative names for the protocol.

p_proto
: The protocol number.

RETURN VALUE

The **getprotoent**(), **getprotobyname**(), and **getprotobynumber**() functions return a pointer to a statically allocated *protoent* structure, or a null pointer if an error occurs or the end of the file is reached.

FILES

/etc/protocols
: protocol database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getprotoent()	Thread safety	MT-Unsafe race:protoent race:protoentbuf locale
getprotobyname()	Thread safety	MT-Unsafe race:protobyname locale
getprotobynumber()	Thread safety	MT-Unsafe race:protobynumber locale
setprotoent(), **endprotoent**()	Thread safety	MT-Unsafe race:protoent locale

In the above table, *protoent* in *race:protoent* signifies that if any of the functions **setprotoent**(), **getprotoent**(), or **endprotoent**() are used in parallel in different threads of a program, then data races could occur.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.3BSD.

SEE ALSO

getnetent(3), *getprotoent_r*(3), *getservent*(3), *protocols*(5)

NAME

getprotoent_r, getprotobyname_r, getprotobynumber_r − get protocol entry (reentrant)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

int getprotoent_r(struct protoent *restrict result_buf,
                  char buf[restrict .buflen], size_t buflen,
                  struct protoent **restrict result);
int getprotobyname_r(const char *restrict name,
                  struct protoent *restrict result_buf,
                  char buf[restrict .buflen], size_t buflen,
                  struct protoent **restrict result);
int getprotobynumber_r(int proto,
                  struct protoent *restrict result_buf,
                  char buf[restrict .buflen], size_t buflen,
                  struct protoent **restrict result);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getprotoent_r(), **getprotobyname_r**(), **getprotobynumber_r**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getprotoent_r**(), **getprotobyname_r**(), and **getprotobynumber_r**() functions are the reentrant equivalents of, respectively, *getprotoent*(3), *getprotobyname*(3), and *getprotobynumber*(3). They differ in the way that the *protoent* structure is returned, and in the function calling signature and return value. This manual page describes just the differences from the nonreentrant functions.

Instead of returning a pointer to a statically allocated *protoent* structure as the function result, these functions copy the structure into the location pointed to by *result_buf*.

The *buf* array is used to store the string fields pointed to by the returned *protoent* structure. (The nonreentrant functions allocate these strings in static storage.) The size of this array is specified in *buflen*. If *buf* is too small, the call fails with the error **ERANGE**, and the caller must try again with a larger buffer. (A buffer of length 1024 bytes should be sufficient for most applications.)

If the function call successfully obtains a protocol record, then **result* is set pointing to *result_buf*; otherwise, **result* is set to NULL.

RETURN VALUE

On success, these functions return 0. On error, they return one of the positive error numbers listed in ERRORS.

On error, record not found (**getprotobyname_r**(), *getprotobynumber_r*()), or end of input (**getprotoent_r**()) *result* is set to NULL.

ERRORS

ENOENT
(**getprotoent_r**()) No more records in database.

ERANGE
buf is too small. Try again with a larger buffer (and increased *buflen*).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getprotoent_r(), **getprotobyname_r**(), **getprotobynumber_r**()	Thread safety	MT-Safe locale

VERSIONS

Functions with similar names exist on some other systems, though typically with different calling signatures.

STANDARDS

GNU.

EXAMPLES

The program below uses **getprotobyname_r**() to retrieve the protocol record for the protocol named in its first command-line argument. If a second (integer) command-line argument is supplied, it is used as the initial value for *buflen*; if **getprotobyname_r**() fails with the error **ERANGE**, the program retries with larger buffer sizes. The following shell session shows a couple of sample runs:

```
$ ./a.out tcp 1
ERANGE! Retrying with larger buffer
getprotobyname_r() returned: 0 (success)  (buflen=78)
p_name=tcp; p_proto=6; aliases=TCP
$ ./a.out xxx 1
ERANGE! Retrying with larger buffer
getprotobyname_r() returned: 0 (success)  (buflen=100)
Call failed/record not found
```

Program source

```
#define _GNU_SOURCE
#include <ctype.h>
#include <errno.h>
#include <netdb.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define MAX_BUF 10000

int
main(int argc, char *argv[])
{
    int buflen, erange_cnt, s;
    struct protoent result_buf;
    struct protoent *result;
    char buf[MAX_BUF];

    if (argc < 2) {
        printf("Usage: %s proto-name [buflen]\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    buflen = 1024;
    if (argc > 2)
        buflen = atoi(argv[2]);

    if (buflen > MAX_BUF) {
        printf("Exceeded buffer limit (%d)\n", MAX_BUF);
        exit(EXIT_FAILURE);
    }

    erange_cnt = 0;
    do {
        s = getprotobyname_r(argv[1], &result_buf,
                             buf, buflen, &result);
        if (s == ERANGE) {
```

```
                if (erange_cnt == 0)
                    printf("ERANGE! Retrying with larger buffer\n");
                erange_cnt++;

                /* Increment a byte at a time so we can see exactly
                   what size buffer was required. */

                buflen++;

                if (buflen > MAX_BUF) {
                    printf("Exceeded buffer limit (%d)\n", MAX_BUF);
                    exit(EXIT_FAILURE);
                }
            }
        } while (s == ERANGE);

        printf("getprotobyname_r() returned: %s  (buflen=%d)\n",
               (s == 0) ? "0 (success)" : (s == ENOENT) ? "ENOENT" :
               strerror(s), buflen);

        if (s != 0 || result == NULL) {
            printf("Call failed/record not found\n");
            exit(EXIT_FAILURE);
        }

        printf("p_name=%s; p_proto=%d; aliases=",
               result_buf.p_name, result_buf.p_proto);
        for (char **p = result_buf.p_aliases; *p != NULL; p++)
            printf("%s ", *p);
        printf("\n");

        exit(EXIT_SUCCESS);
    }
```

NAME

getpt − open a new pseudoterminal master

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <stdlib.h>

int getpt(void);
```

DESCRIPTION

getpt() opens a new pseudoterminal device and returns a file descriptor that refers to that device. It is equivalent to opening the pseudoterminal multiplexor device

```
open("/dev/ptmx", O_RDWR);
```

on Linux systems, though the pseudoterminal multiplexor device is located elsewhere on some systems that use the GNU C library.

RETURN VALUE

getpt() returns an open file descriptor upon successful completion. Otherwise, it returns −1 and sets *errno* to indicate the error.

ERRORS

getpt() can fail with various errors described in *open*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getpt()	Thread safety	MT-Safe

VERSIONS

Use *posix_openpt*(3) instead.

STANDARDS

GNU.

HISTORY

glibc 2.1.

SEE ALSO

grantpt(3), *posix_openpt*(3), *ptsname*(3), *unlockpt*(3), *ptmx*(4), *pty*(7)

NAME

getpw − reconstruct password line entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <sys/types.h>
#include <pwd.h>

[[deprecated]] int getpw(uid_t uid, char *buf);
```

DESCRIPTION

The **getpw**() function reconstructs the password line entry for the given user ID *uid* in the buffer *buf*. The returned buffer contains a line of format

```
name:passwd:uid:gid:gecos:dir:shell
```

The *passwd* structure is defined in <*pwd.h*> as follows:

```
struct passwd {
    char   *pw_name;       /* username */
    char   *pw_passwd;     /* user password */
    uid_t   pw_uid;        /* user ID */
    gid_t   pw_gid;        /* group ID */
    char   *pw_gecos;      /* user information */
    char   *pw_dir;        /* home directory */
    char   *pw_shell;      /* shell program */
};
```

For more information about the fields of this structure, see *passwd*(5).

RETURN VALUE

The **getpw**() function returns 0 on success; on error, it returns −1, and *errno* is set to indicate the error.

If *uid* is not found in the password database, **getpw**() returns −1, sets *errno* to 0, and leaves *buf* unchanged.

ERRORS

0 or **ENOENT**
: No user corresponding to *uid*.

EINVAL
: *buf* is NULL.

ENOMEM
: Insufficient memory to allocate *passwd* structure.

FILES

/etc/passwd
: password database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getpw()	Thread safety	MT-Safe locale

STANDARDS

None.

HISTORY

SVr2.

BUGS

The **getpw**() function is dangerous as it may overflow the provided buffer *buf*. It is obsoleted by *getpwuid*(3).

SEE ALSO

endpwent(3), *fgetpwent*(3), *getpwent*(3), *getpwnam*(3), *getpwuid*(3), *putpwent*(3), *setpwent*(3), *passwd*(5)

NAME

getpwent, setpwent, endpwent − get password file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <pwd.h>

struct passwd *getpwent(void);
void setpwent(void);
void endpwent(void);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getpwent(), **setpwent**(), **endpwent**():
_XOPEN_SOURCE >= 500
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getpwent**() function returns a pointer to a structure containing the broken-out fields of a record from the password database (e.g., the local password file */etc/passwd*, NIS, and LDAP). The first time **getpwent**() is called, it returns the first entry; thereafter, it returns successive entries.

The **setpwent**() function rewinds to the beginning of the password database.

The **endpwent**() function is used to close the password database after all processing has been performed.

The *passwd* structure is defined in <*pwd.h*> as follows:

```
struct passwd {
    char   *pw_name;       /* username */
    char   *pw_passwd;     /* user password */
    uid_t   pw_uid;        /* user ID */
    gid_t   pw_gid;        /* group ID */
    char   *pw_gecos;      /* user information */
    char   *pw_dir;        /* home directory */
    char   *pw_shell;      /* shell program */
};
```

For more information about the fields of this structure, see *passwd*(5).

RETURN VALUE

The **getpwent**() function returns a pointer to a *passwd* structure, or NULL if there are no more entries or an error occurred. If an error occurs, *errno* is set to indicate the error. If one wants to check *errno* after the call, it should be set to zero before the call.

The return value may point to a static area, and may be overwritten by subsequent calls to **getpwent**(), *getpwnam*(3), or *getpwuid*(3). (Do not pass the returned pointer to *free*(3).)

ERRORS

EINTR
A signal was caught; see *signal*(7).

EIO I/O error.

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOMEM
Insufficient memory to allocate *passwd* structure.

ERANGE
Insufficient buffer space supplied.

FILES

/etc/passwd
local password database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getpwent()	Thread safety	MT-Unsafe race:pwent race:pwentbuf locale
setpwent(), **endpwent**()	Thread safety	MT-Unsafe race:pwent locale

In the above table, *pwent* in *race:pwent* signifies that if any of the functions **setpwent**(), **getpwent**(), or **endpwent**() are used in parallel in different threads of a program, then data races could occur.

VERSIONS

The *pw_gecos* field is not specified in POSIX, but is present on most implementations.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

SEE ALSO

fgetpwent(3), *getpw*(3), *getpwent_r*(3), *getpwnam*(3), *getpwuid*(3), *putpwent*(3), *passwd*(5)

NAME

getpwent_r, fgetpwent_r − get passwd file entry reentrantly

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <pwd.h>

int getpwent_r(struct passwd *restrict pwbuf,
               char buf[restrict .buflen], size_t buflen,
               struct passwd **restrict pwbufp);
int fgetpwent_r(FILE *restrict stream, struct passwd *restrict pwbuf,
               char buf[restrict .buflen], size_t buflen,
               struct passwd **restrict pwbufp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getpwent_r(),
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

fgetpwent_r():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

The functions **getpwent_r**() and **fgetpwent_r**() are the reentrant versions of *getpwent*(3) and *fgetpwent*(3). The former reads the next passwd entry from the stream initialized by *setpwent*(3). The latter reads the next passwd entry from *stream*.

The *passwd* structure is defined in <*pwd.h*> as follows:

```
struct passwd {
    char    *pw_name;       /* username */
    char    *pw_passwd;     /* user password */
    uid_t    pw_uid;        /* user ID */
    gid_t    pw_gid;        /* group ID */
    char    *pw_gecos;      /* user information */
    char    *pw_dir;        /* home directory */
    char    *pw_shell;      /* shell program */
};
```

For more information about the fields of this structure, see *passwd*(5).

The nonreentrant functions return a pointer to static storage, where this static storage contains further pointers to user name, password, gecos field, home directory and shell. The reentrant functions described here return all of that in caller-provided buffers. First of all there is the buffer *pwbuf* that can hold a *struct passwd*. And next the buffer *buf* of size *buflen* that can hold additional strings. The result of these functions, the *struct passwd* read from the stream, is stored in the provided buffer **pwbuf*, and a pointer to this *struct passwd* is returned in **pwbufp*.

RETURN VALUE

On success, these functions return 0 and **pwbufp* is a pointer to the *struct passwd*. On error, these functions return an error value and **pwbufp* is NULL.

ERRORS

ENOENT
No more entries.

ERANGE
Insufficient buffer space supplied. Try again with larger buffer.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getpwent_r()	Thread safety	MT-Unsafe race:pwent locale
fgetpwent_r()	Thread safety	MT-Safe

In the above table, *pwent* in *race:pwent* signifies that if any of the functions **setpwent**(), **getpwent**(), **endpwent**(), or **getpwent_r**() are used in parallel in different threads of a program, then data races could occur.

VERSIONS

Other systems use the prototype

```
struct passwd *
getpwent_r(struct passwd *pwd, char *buf, int buflen);
```

or, better,

```
int
getpwent_r(struct passwd *pwd, char *buf, int buflen,
           FILE **pw_fp);
```

STANDARDS

None.

HISTORY

These functions are done in a style resembling the POSIX version of functions like *getpwnam_r*(3).

NOTES

The function **getpwent_r**() is not really reentrant since it shares the reading position in the stream with all other threads.

EXAMPLES

```
#define _GNU_SOURCE
#include <pwd.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>

#define BUFLEN 4096

int
main(void)
{
    struct passwd pw;
    struct passwd *pwp;
    char buf[BUFLEN];
    int i;

    setpwent();
    while (1) {
        i = getpwent_r(&pw, buf, sizeof(buf), &pwp);
        if (i)
            break;
        printf("%s (%jd)\tHOME %s\tSHELL %s\n", pwp->pw_name,
               (intmax_t) pwp->pw_uid, pwp->pw_dir, pwp->pw_shell);
    }
    endpwent();
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

fgetpwent(3), *getpw*(3), *getpwent*(3), *getpwnam*(3), *getpwuid*(3), *putpwent*(3), *passwd*(5)

NAME

getpwnam, getpwnam_r, getpwuid, getpwuid_r − get password file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <pwd.h>

struct passwd *getpwnam(const char *name);
struct passwd *getpwuid(uid_t uid);

int getpwnam_r(const char *restrict name, struct passwd *restrict pwd,
        char buf[restrict .buflen], size_t buflen,
        struct passwd **restrict result);
int getpwuid_r(uid_t uid, struct passwd *restrict pwd,
        char buf[restrict .buflen], size_t buflen,
        struct passwd **restrict result);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getpwnam_r(), **getpwuid_r**():
_POSIX_C_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getpwnam**() function returns a pointer to a structure containing the broken-out fields of the record in the password database (e.g., the local password file */etc/passwd*, NIS, and LDAP) that matches the username *name*.

The **getpwuid**() function returns a pointer to a structure containing the broken-out fields of the record in the password database that matches the user ID *uid*.

The *passwd* structure is defined in <*pwd.h*> as follows:

```
struct passwd {
    char   *pw_name;       /* username */
    char   *pw_passwd;     /* user password */
    uid_t   pw_uid;        /* user ID */
    gid_t   pw_gid;        /* group ID */
    char   *pw_gecos;      /* user information */
    char   *pw_dir;        /* home directory */
    char   *pw_shell;      /* shell program */
};
```

See *passwd*(5) for more information about these fields.

The **getpwnam_r**() and **getpwuid_r**() functions obtain the same information as **getpwnam**() and **getpwuid**(), but store the retrieved *passwd* structure in the space pointed to by *pwd*. The string fields pointed to by the members of the *passwd* structure are stored in the buffer *buf* of size *buflen*. A pointer to the result (in case of success) or NULL (in case no entry was found or an error occurred) is stored in **result*.

The call

```
sysconf(_SC_GETPW_R_SIZE_MAX)
```

returns either −1, without changing *errno*, or an initial suggested size for *buf*. (If this size is too small, the call fails with **ERANGE**, in which case the caller can retry with a larger buffer.)

RETURN VALUE

The **getpwnam**() and **getpwuid**() functions return a pointer to a *passwd* structure, or NULL if the matching entry is not found or an error occurs. If an error occurs, *errno* is set to indicate the error. If one wants to check *errno* after the call, it should be set to zero before the call.

The return value may point to a static area, and may be overwritten by subsequent calls to *getpwent*(3), **getpwnam**(), or **getpwuid**(). (Do not pass the returned pointer to *free*(3).)

On success, **getpwnam_r**() and **getpwuid_r**() return zero, and set **result* to *pwd*. If no matching password record was found, these functions return 0 and store NULL in **result*. In case of error, an error number is returned, and NULL is stored in **result*.

ERRORS

0 or **ENOENT** or **ESRCH** or **EBADF** or **EPERM** or ...
The given *name* or *uid* was not found.

EINTR
A signal was caught; see *signal*(7).

EIO I/O error.

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOMEM
Insufficient memory to allocate *passwd* structure.

ERANGE
Insufficient buffer space supplied.

FILES

/etc/passwd
local password database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getpwnam()	Thread safety	MT-Unsafe race:pwnam locale
getpwuid()	Thread safety	MT-Unsafe race:pwuid locale
getpwnam_r(), **getpwuid_r**()	Thread safety	MT-Safe locale

VERSIONS

The *pw_gecos* field is not specified in POSIX, but is present on most implementations.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

NOTES

The formulation given above under "RETURN VALUE" is from POSIX.1-2001. It does not call "not found" an error, and hence does not specify what value *errno* might have in this situation. But that makes it impossible to recognize errors. One might argue that according to POSIX *errno* should be left unchanged if an entry is not found. Experiments on various UNIX-like systems show that lots of different values occur in this situation: 0, ENOENT, EBADF, ESRCH, EWOULDBLOCK, EPERM, and probably others.

The *pw_dir* field contains the name of the initial working directory of the user. Login programs use the value of this field to initialize the **HOME** environment variable for the login shell. An application that wants to determine its user's home directory should inspect the value of **HOME** (rather than the value *getpwuid(getuid())−>pw_dir*) since this allows the user to modify their notion of "the home directory" during a login session. To determine the (initial) home directory of another user, it is necessary to use *getpwnam("username")−>pw_dir* or similar.

EXAMPLES

The program below demonstrates the use of **getpwnam_r**() to find the full username and user ID for the username supplied as a command-line argument.

```
#include <errno.h>
#include <pwd.h>
#include <stdint.h>
```

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    struct passwd pwd;
    struct passwd *result;
    char *buf;
    long bufsize;
    int s;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s username\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    bufsize = sysconf(_SC_GETPW_R_SIZE_MAX);
    if (bufsize == -1)          /* Value was indeterminate */
        bufsize = 16384;        /* Should be more than enough */

    buf = malloc(bufsize);
    if (buf == NULL) {
        perror("malloc");
        exit(EXIT_FAILURE);
    }

    s = getpwnam_r(argv[1], &pwd, buf, bufsize, &result);
    if (result == NULL) {
        if (s == 0)
            printf("Not found\n");
        else {
            errno = s;
            perror("getpwnam_r");
        }
        exit(EXIT_FAILURE);
    }

    printf("Name: %s; UID: %jd\n", pwd.pw_gecos,
           (intmax_t) pwd.pw_uid);
    exit(EXIT_SUCCESS);
}
```

NAME

getrpcent, getrpcbyname, getrpcbynumber, setrpcent, endrpcent − get RPC entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

struct rpcent *getrpcent(void);

struct rpcent *getrpcbyname(const char *name);
struct rpcent *getrpcbynumber(int number);

void setrpcent(int stayopen);
void endrpcent(void);
```

DESCRIPTION

The **getrpcent**(), **getrpcbyname**(), and **getrpcbynumber**() functions each return a pointer to an object with the following structure containing the broken-out fields of an entry in the RPC program number data base.

```
struct rpcent {
    char  *r_name;     /* name of server for this RPC program */
    char **r_aliases;  /* alias list */
    long   r_number;   /* RPC program number */
};
```

The members of this structure are:

r_name The name of the server for this RPC program.

r_aliases
: A NULL-terminated list of alternate names for the RPC program.

r_number
: The RPC program number for this service.

The **getrpcent**() function reads the next entry from the database. A connection is opened to the database if necessary.

The **setrpcent**() function opens a connection to the database, and sets the next entry to the first entry. If *stayopen* is nonzero, then the connection to the database will not be closed between calls to one of the **getrpc***() functions.

The **endrpcent**() function closes the connection to the database.

The **getrpcbyname**() and **getrpcbynumber**() functions sequentially search from the beginning of the file until a matching RPC program name or program number is found, or until end-of-file is encountered.

RETURN VALUE

On success, **getrpcent**(), **getrpcbyname**(), and **getrpcbynumber**() return a pointer to a statically allocated *rpcent* structure. NULL is returned on EOF or error.

FILES

/etc/rpc
: RPC program number database.

NAME

getrpcent_r, getrpcbyname_r, getrpcbynumber_r − get RPC entry (reentrant)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

int getrpcent_r(struct rpcent *result_buf, char buf[.buflen],
                size_t buflen, struct rpcent **result);
int getrpcbyname_r(const char *name,
                struct rpcent *result_buf, char buf[.buflen],
                size_t buflen, struct rpcent **result);
int getrpcbynumber_r(int number,
                struct rpcent *result_buf, char buf[.buflen],
                size_t buflen, struct rpcent **result);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getrpcent_r(), **getrpcbyname_r**(), **getrpcbynumber_r**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getrpcent_r**(), **getrpcbyname_r**(), and **getrpcbynumber_r**() functions are the reentrant equivalents of, respectively, *getrpcent*(3), *getrpcbyname*(3), and *getrpcbynumber*(3). They differ in the way that the *rpcent* structure is returned, and in the function calling signature and return value. This manual page describes just the differences from the nonreentrant functions.

Instead of returning a pointer to a statically allocated *rpcent* structure as the function result, these functions copy the structure into the location pointed to by *result_buf*.

The *buf* array is used to store the string fields pointed to by the returned *rpcent* structure. (The nonreentrant functions allocate these strings in static storage.) The size of this array is specified in *buflen*. If *buf* is too small, the call fails with the error **ERANGE**, and the caller must try again with a larger buffer. (A buffer of length 1024 bytes should be sufficient for most applications.)

If the function call successfully obtains an RPC record, then **result* is set pointing to *result_buf*; otherwise, **result* is set to NULL.

RETURN VALUE

On success, these functions return 0. On error, they return one of the positive error numbers listed in ERRORS.

On error, record not found (**getrpcbyname_r**(), *getrpcbynumber_r*()), or end of input (**getrpcent_r**()) *result* is set to NULL.

ERRORS

ENOENT
(**getrpcent_r**()) No more records in database.

ERANGE
buf is too small. Try again with a larger buffer (and increased *buflen*).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getrpcent_r(), **getrpcbyname_r**(), **getrpcbynumber_r**()	Thread safety	MT-Safe locale

VERSIONS

Functions with similar names exist on some other systems, though typically with different calling signatures.

STANDARDS

GNU.

NAME

getrpcport − get RPC port number

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <rpc/rpc.h>

int getrpcport(const char ****host*, unsigned long** *prognum***,**
unsigned long *versnum***, unsigned int** *proto***);**

DESCRIPTION

getrpcport() returns the port number for version *versnum* of the RPC program *prognum* running on *host* and using protocol *proto*. It returns 0 if it cannot contact the portmapper, or if *prognum* is not registered. If *prognum* is registered but not with version *versnum*, it will still return a port number (for some version of the program) indicating that the program is indeed registered. The version mismatch will be detected upon the first call to the service.

ATTRIBUTES

BSD, Solaris.

NAME

gets − get a string from standard input (DEPRECATED)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

[[deprecated]] char *gets(char *s);

DESCRIPTION

Never use this function.

gets() reads a line from *stdin* into the buffer pointed to by *s* until either a terminating newline or **EOF**, which it replaces with a null byte ('\0'). No check for buffer overrun is performed (see BUGS below).

RETURN VALUE

gets() returns *s* on success, and NULL on error or when end of file occurs while no characters have been read. However, given the lack of buffer overrun checking, there can be no guarantees that the function will even return.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gets()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

C89, POSIX.1-2001.

LSB deprecates **gets**(). POSIX.1-2008 marks **gets**() obsolescent. ISO C11 removes the specification of **gets**() from the C language, and since glibc 2.16, glibc header files don't expose the function declaration if the **_ISOC11_SOURCE** feature test macro is defined.

BUGS

Never use **gets**(). Because it is impossible to tell without knowing the data in advance how many characters **gets**() will read, and because **gets**() will continue to store characters past the end of the buffer, it is extremely dangerous to use. It has been used to break computer security. Use **fgets**() instead.

For more information, see CWE-242 (aka "Use of Inherently Dangerous Function") at http://cwe.mitre.org/data/definitions/242.html

NAME

getservent, getservbyname, getservbyport, setservent, endservent − get service entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <netdb.h>

struct servent *getservent(void);

struct servent *getservbyname(const char * *name***, const char *** *proto***);**
struct servent *getservbyport(int *port***, const char *** *proto***);**

void setservent(int *stayopen***);**
void endservent(void);

DESCRIPTION

The **getservent**() function reads the next entry from the services database (see *services*(5)) and returns a *servent* structure containing the broken-out fields from the entry. A connection is opened to the database if necessary.

The **getservbyname**() function returns a *servent* structure for the entry from the database that matches the service *name* using protocol *proto*. If *proto* is NULL, any protocol will be matched. A connection is opened to the database if necessary.

The **getservbyport**() function returns a *servent* structure for the entry from the database that matches the port *port* (given in network byte order) using protocol *proto*. If *proto* is NULL, any protocol will be matched. A connection is opened to the database if necessary.

The **setservent**() function opens a connection to the database, and sets the next entry to the first entry. If *stayopen* is nonzero, then the connection to the database will not be closed between calls to one of the **getserv***() functions.

The **endservent**() function closes the connection to the database.

The *servent* structure is defined in <*netdb.h*> as follows:

```
struct servent {
    char  *s_name;       /* official service name */
    char **s_aliases;    /* alias list */
    int    s_port;       /* port number */
    char  *s_proto;      /* protocol to use */
}
```

The members of the *servent* structure are:

s_name
: The official name of the service.

s_aliases
: A NULL-terminated list of alternative names for the service.

s_port The port number for the service given in network byte order.

s_proto The name of the protocol to use with this service.

RETURN VALUE

The **getservent**(), **getservbyname**(), and **getservbyport**() functions return a pointer to a statically allocated *servent* structure, or NULL if an error occurs or the end of the file is reached.

FILES

/etc/services
: services database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getservent()	Thread safety	MT-Unsafe race:servent race:serventbuf locale
getservbyname()	Thread safety	MT-Unsafe race:servbyname locale
getservbyport()	Thread safety	MT-Unsafe race:servbyport locale
setservent(), **endservent**()	Thread safety	MT-Unsafe race:servent locale

In the above table, *servent* in *race:servent* signifies that if any of the functions **setservent**(), **getservent**(), or **endservent**() are used in parallel in different threads of a program, then data races could occur.

STANDARDS

NAME

getservent_r, getservbyname_r, getservbyport_r − get service entry (reentrant)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

int getservent_r(struct servent *restrict result_buf,
                 char buf[restrict .buflen], size_t buflen,
                 struct servent **restrict result);
int getservbyname_r(const char *restrict name,
                 const char *restrict proto,
                 struct servent *restrict result_buf,
                 char buf[restrict .buflen], size_t buflen,
                 struct servent **restrict result);
int getservbyport_r(int port,
                 const char *restrict proto,
                 struct servent *restrict result_buf,
                 char buf[restrict .buflen], size_t buflen,
                 struct servent **restrict result);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getservent_r(), **getservbyname_r**(), **getservbyport_r**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **getservent_r**(), **getservbyname_r**(), and **getservbyport_r**() functions are the reentrant equivalents of, respectively, *getservent*(3), *getservbyname*(3), and *getservbyport*(3). They differ in the way that the *servent* structure is returned, and in the function calling signature and return value. This manual page describes just the differences from the nonreentrant functions.

Instead of returning a pointer to a statically allocated *servent* structure as the function result, these functions copy the structure into the location pointed to by *result_buf*.

The *buf* array is used to store the string fields pointed to by the returned *servent* structure. (The nonreentrant functions allocate these strings in static storage.) The size of this array is specified in *buflen*. If *buf* is too small, the call fails with the error **ERANGE**, and the caller must try again with a larger buffer. (A buffer of length 1024 bytes should be sufficient for most applications.)

If the function call successfully obtains a service record, then **result* is set pointing to *result_buf*; otherwise, **result* is set to NULL.

RETURN VALUE

On success, these functions return 0. On error, they return one of the positive error numbers listed in errors.

On error, record not found (**getservbyname_r**(), *getservbyport_r*()), or end of input (**getservent_r**()) *result* is set to NULL.

ERRORS

ENOENT
(**getservent_r**()) No more records in database.

ERANGE
buf is too small. Try again with a larger buffer (and increased *buflen*).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getservent_r(), **getservbyname_r**(), **getservbyport_r**()	Thread safety	MT-Safe locale

VERSIONS

Functions with similar names exist on some other systems, though typically with different calling signatures.

STANDARDS

GNU.

EXAMPLES

The program below uses **getservbyport_r**() to retrieve the service record for the port and protocol named in its first command-line argument. If a third (integer) command-line argument is supplied, it is used as the initial value for *buflen*; if **getservbyport_r**() fails with the error **ERANGE**, the program retries with larger buffer sizes. The following shell session shows a couple of sample runs:

```
$ ./a.out 7 tcp 1
ERANGE! Retrying with larger buffer
getservbyport_r() returned: 0 (success)  (buflen=87)
s_name=echo; s_proto=tcp; s_port=7; aliases=
$ ./a.out 77777 tcp
getservbyport_r() returned: 0 (success)  (buflen=1024)
Call failed/record not found
```

Program source

```
#define _GNU_SOURCE
#include <ctype.h>
#include <errno.h>
#include <netdb.h>
#include <stdio.h>

```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getspent_r(), **getspnam_r**(), **fgetspent_r**(), **sgetspent_r**():
- Since glibc 2.19:
  - _DEFAULT_SOURCE
- glibc 2.19 and earlier:
  - _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

Long ago it was considered safe to have encrypted passwords openly visible in the password file. When computers got faster and people got more security-conscious, this was no longer acceptable. Julianne Frances Haugh implemented the shadow password suite that keeps the encrypted passwords in the shadow password database (e.g., the local shadow password file */etc/shadow*, NIS, and LDAP), readable only by root.

The functions described below resemble those for the traditional password database (e.g., see *getpwnam*(3) and *getpwent*(3)).

The **getspnam**() function returns a pointer to a structure containing the broken-out fields of the record in the shadow password database that matches the username *name*.

The **getspent**() function returns a pointer to the next entry in the shadow password database. The position in the input stream is initialized by **setspent**(). When done reading, the program may call **endspent**() so that resources can be deallocated.

The **fgetspent**() function is similar to **getspent**() but uses the supplied stream instead of the one implicitly opened by **setspent**().

The **sgetspent**() function parses the supplied string *s* into a struct *spwd*.

The **putspent**() function writes the contents of the supplied struct *spwd *p* as a text line in the shadow password file format to *stream*. String entries with value NULL and numerical entries with value −1

are written as an empty string.

The **lckpwdf**() function is intended to protect against multiple simultaneous accesses of the shadow password database. It tries to acquire a lock, and returns 0 on success, or −1 on failure (lock not obtained within 15 seconds). The **ulckpwdf**() function releases the lock again. Note that there is no protection against direct access of the shadow password file. Only programs that use **lckpwdf**() will notice the lock.

These were the functions that formed the original shadow API. They are widely available.

Reentrant versions

Analogous to the reentrant functions for the password database, glibc also has reentrant functions for the shadow password database. The **getspnam_r**() function is like **getspnam**() but stores the retrieved shadow password structure in the space pointed to by *spbuf*. This shadow password structure contains pointers to strings, and these strings are stored in the buffer *buf* of size *buflen*. A pointer to the result (in case of success) or NULL (in case no entry was found or an error occurred) is stored in **spbufp*.

The functions **getspent_r**(), **fgetspent_r**(), and **sgetspent_r**() are similarly analogous to their nonreentrant counterparts.

Some non-glibc systems also have functions with these names, often with different prototypes.

Structure

The shadow password structure is defined in <*shadow.h*> as follows:

```
struct spwd {
    char *sp_namp;     /* Login name */
    char *sp_pwdp;     /* Encrypted password */
    long  sp_lstchg;   /* Date of last change
                          (measured in days since
                          1970-01-01 00:00:00 +0000 (UTC)) */
    long  sp_min;      /* Min # of days between changes */
    long  sp_max;      /* Max # of days between changes */
    long  sp_warn;     /* # of days before password expires
                          to warn user to change it */
    long  sp_inact;    /* # of days after password expires
                          until account is disabled */
    long  sp_expire;   /* Date when account expires
                          (measured in days since
                          1970-01-01 00:00:00 +0000 (UTC)) */
    unsigned long sp_flag;  /* Reserved */
};
```

RETURN VALUE

The functions that return a pointer return NULL if no more entries are available or if an error occurs during processing. The functions which have *int* as the return value return 0 for success and −1 for failure, with *errno* set to indicate the error.

For the nonreentrant functions, the return value may point to static area, and may be overwritten by subsequent calls to these functions.

The reentrant functions return zero on success. In case of error, an error number is returned.

ERRORS

EACCES
The caller does not have permission to access the shadow password file.

ERANGE
Supplied buffer is too small.

FILES

/etc/shadow
local shadow password database file

/etc/.pwd.lock
lock file

The include file <*paths.h*> defines the constant **_PATH_SHADOW** to the pathname of the shadow

password file.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

getsubopt − parse suboption arguments from a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int getsubopt(char **restrict optionp, char *const *restrict tokens,
        char **restrict valuep);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getsubopt():
  _XOPEN_SOURCE >= 500
    || /* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L

DESCRIPTION

getsubopt() parses the list of comma-separated suboptions provided in *optionp*. (Such a suboption list is typically produced when *getopt*(3) is used to parse a command line; see for example the *−o* option of *mount*(8)Each suboption may include an associated value, which is separated from the suboption name by an equal sign. The following is an example of the kind of string that might be passed in *optionp*:

```
ro,name=xyz
```

The *tokens* argument is a pointer to a NULL-terminated array of pointers to the tokens that **getsubopt**() will look for in *optionp*. The tokens should be distinct, null-terminated strings containing at least one character, with no embedded equal signs or commas.

Each call to **getsubopt**() returns information about the next unprocessed suboption in *optionp*. The first equal sign in a suboption (if any) is interpreted as a separator between the name and the value of that suboption. The value extends to the next comma, or (for the last suboption) to the end of the string. If the name of the suboption matches a known name from *tokens*, and a value string was found, **getsubopt**() sets **valuep* to the address of that string. The first comma in *optionp* is overwritten with a null byte, so **valuep* is precisely the "value string" for that suboption.

If the suboption is recognized, but no value string was found, **valuep* is set to NULL.

When **getsubopt**() returns, *optionp* points to the next suboption, or to the null byte ('\0') at the end of the string if the last suboption was just processed.

RETURN VALUE

If the first suboption in *optionp* is recognized, **getsubopt**() returns the index of the matching suboption element in *tokens*. Otherwise, −1 is returned and **valuep* is the entire *name***[**=*value***]** string.

Since **optionp* is changed, the first suboption before the call to **getsubopt**() is not (necessarily) the same as the first suboption after **getsubopt**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getsubopt()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

Since **getsubopt**() overwrites any commas it finds in the string **optionp*, that string must be writable; it cannot be a string constant.

EXAMPLES

The following program expects suboptions following a "−o" option.

```
#define _XOPEN_SOURCE 500
#include <stdio.h>
#include <stdlib.h>
```

```
#include <assert.h>

int
main(int argc, char *argv[])
{
    enum {
        RO_OPT = 0,
        RW_OPT,
        NAME_OPT
    };
    char *const token[] = {
        [RO_OPT]   = "ro",
        [RW_OPT]   = "rw",
        [NAME_OPT] = "name",
        NULL
    };
    char *subopts;
    char *value;
    int opt;

    int readonly = 0;
    int readwrite = 0;
    char *name = NULL;
    int errfnd = 0;

    while ((opt = getopt(argc, argv, "o:")) != -1) {
        switch (opt) {
        case 'o':
            subopts = optarg;
            while (*subopts != '\0' && !errfnd) {

                switch (getsubopt(&subopts, token, &value)) {
                case RO_OPT:
                    readonly = 1;
                    break;

                case RW_OPT:
                    readwrite = 1;
                    break;

                case NAME_OPT:
                    if (value == NULL) {
                        fprintf(stderr,
                                "Missing value for suboption '%s'\n",
                                token[NAME_OPT]);
                        errfnd = 1;
                        continue;
                    }

                    name = value;
                    break;

                default:
                    fprintf(stderr,
                            "No match found for token: /%s/\n", value);
                    errfnd = 1;
                    break;
                }
```

```
                }
                if (readwrite && readonly) {
                    fprintf(stderr,
                            "Only one of '%s' and '%s' can be specified\n",
                            token[RO_OPT], token[RW_OPT]);
                    errfnd = 1;
                }
                break;

            default:
                errfnd = 1;
            }
        }

        if (errfnd || argc == 1) {
            fprintf(stderr, "\nUsage: %s −o <suboptstring>\n", argv[0]);
            fprintf(stderr,
                    "suboptions are 'ro', 'rw', and 'name=<value>'\n");
            exit(EXIT_FAILURE);
        }

        /* Remainder of program... */

        exit(EXIT_SUCCESS);
    }
```

getopt(3)

NAME

getttyent, getttynam, setttyent, endttyent − get ttys file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <ttyent.h>

struct ttyent *getttyent(void);
struct ttyent *getttynam(const char *_name_);

int setttyent(void);
int endttyent(void);

DESCRIPTION

These functions provide an interface to the file **_PATH_TTYS** (e.g., */etc/ttys*).

The function **setttyent**() opens the file or rewinds it if already open.

The function **endttyent**() closes the file.

The function **getttynam**() searches for a given terminal name in the file. It returns a pointer to a *ttyent* structure (description below).

The function **getttyent**() opens the file **_PATH_TTYS** (if necessary) and returns the first entry. If the file is already open, the next entry. The *ttyent* structure has the form:

```
struct ttyent {
    char *ty_name;     /* terminal device name */
    char *ty_getty;    /* command to execute, usually getty */
    char *ty_type;     /* terminal type for termcap */
    int   ty_status;   /* status flags */
    char *ty_window;   /* command to start up window manager */
    char *ty_comment;  /* comment field */
};
```

ty_status can be:

```
#define TTY_ON     0x01  /* enable logins (start ty_getty program) */
#define TTY_SECURE 0x02  /* allow UID 0 to login */
```

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getttyent(), **setttyent**(), **endttyent**(), **getttynam**()	Thread safety	MT-Unsafe race:ttyent

STANDARDS

BSD.

NOTES

Under Linux, the file */etc/ttys*, and the functions described above, are not used.

NAME

getusershell, setusershell, endusershell − get permitted user shells

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

char *getusershell(void);
void setusershell(void);
void endusershell(void);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getusershell(), **setusershell**(), **endusershell**():
Since glibc 2.21:
_DEFAULT_SOURCE
In glibc 2.19 and 2.20:
_DEFAULT_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)
Up to and including glibc 2.19:
_BSD_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)

DESCRIPTION

The **getusershell**() function returns the next line from the file */etc/shells*, opening the file if necessary. The line should contain the pathname of a valid user shell. If */etc/shells* does not exist or is unreadable, **getusershell**() behaves as if */bin/sh* and */bin/csh* were listed in the file.

The **setusershell**() function rewinds */etc/shells*.

The **endusershell**() function closes */etc/shells*.

RETURN VALUE

The **getusershell**() function returns NULL on end-of-file.

FILES

/etc/shells

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

getutent, getutid, getutline, pututline, setutent, endutent, utmpname − access utmp file entries

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <utmp.h>

struct utmp *getutent(void);
struct utmp *getutid(const struct utmp *ut);
struct utmp *getutline(const struct utmp *ut);

struct utmp *pututline(const struct utmp *ut);

void setutent(void);
void endutent(void);

int utmpname(const char * file);
```

DESCRIPTION

New applications should use the POSIX.1-specified "utmpx" versions of these functions; see STANDARDS.

utmpname() sets the name of the utmp-format file for the other utmp functions to access. If **utmpname**() is not used to set the filename before the other functions are used, they assume **_PATH_UTMP**, as defined in <*paths.h*>.

setutent() rewinds the file pointer to the beginning of the utmp file. It is generally a good idea to call it before any of the other functions.

endutent() closes the utmp file. It should be called when the user code is done accessing the file with the other functions.

getutent() reads a line from the current file position in the utmp file. It returns a pointer to a structure containing the fields of the line. The definition of this structure is shown in *utmp*(5).

getutid() searches forward from the current file position in the utmp file based upon *ut*. If *ut−>ut_type* is one of **RUN_LVL**, **BOOT_TIME**, **NEW_TIME**, or **OLD_TIME**, **getutid**() will find the first entry whose *ut_type* field matches *ut−>ut_type*. If *ut−>ut_type* is one of **INIT_PROCESS**, **LOGIN_PROCESS**, **USER_PROCESS**, or **DEAD_PROCESS**, **getutid**() will find the first entry whose *ut_id* field matches *ut−>ut_id*.

getutline() searches forward from the current file position in the utmp file. It scans entries whose *ut_type* is **USER_PROCESS** or **LOGIN_PROCESS** and returns the first one whose *ut_line* field matches *ut−>ut_line*.

pututline() writes the *utmp* structure *ut* into the utmp file. It uses **getutid**() to search for the proper place in the file to insert the new entry. If it cannot find an appropriate slot for *ut*, **pututline**() will append the new entry to the end of the file.

RETURN VALUE

getutent(), **getutid**(), and **getutline**() return a pointer to a *struct utmp* on success, and NULL on failure (which includes the "record not found" case). This *struct utmp* is allocated in static storage, and may be overwritten by subsequent calls.

On success **pututline**() returns *ut*; on failure, it returns NULL.

utmpname() returns 0 if the new name was successfully stored, or −1 on failure.

On failure, these functions *errno* set to indicate the error.

ERRORS

ENOMEM
: Out of memory.

ESRCH
: Record not found.

setutent(), **pututline**(), and the **getut***() functions can also fail for the reasons described in *open*(2).

FILES

/var/run/utmp
database of currently logged-in users

/var/log/wtmp
database of past user logins

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getutent()	Thread safety	MT-Unsafe init race:utent race:utentbuf sig:ALRM timer
getutid(), **getutline**()	Thread safety	MT-Unsafe init race:utent sig:ALRM timer
pututline()	Thread safety	MT-Unsafe race:utent sig:ALRM timer
setutent(), **endutent**(), **utmpname**()	Thread safety	MT-Unsafe race:utent

In the above table, *utent* in *race:utent* signifies that if any of the functions **setutent**(), **getutent**(), **getutid**(), **getutline**(), **pututline**(), **utmpname**(), or **endutent**() are used in parallel in different threads of a program, then data races could occur.

STANDARDS

None.

HISTORY

XPG2, SVr4.

In XPG2 and SVID 2 the function **pututline**() is documented to return void, and that is what it does on many systems (AIX, HP-UX). HP-UX introduces a new function **_pututline**() with the prototype given above for **pututline**().

All these functions are obsolete now on non-Linux systems. POSIX.1-2001 and POSIX.1-2008, following SUSv1, does not have any of these functions, but instead uses

```
#include <utmpx.h>

struct utmpx *getutxent(void);
struct utmpx *getutxid(const struct utmpx *);
struct utmpx *getutxline(const struct utmpx *);
struct utmpx *pututxline(const struct utmpx *);
void setutxent(void);
void endutxent(void);
```

These functions are provided by glibc, and perform the same task as their equivalents without the "x", but use *struct utmpx*, defined on Linux to be the same as *struct utmp*. For completeness, glibc also provides **utmpxname**(), although this function is not specified by POSIX.1.

On some other systems, the *utmpx* structure is a superset of the *utmp* structure, with additional fields, and larger versions of the existing fields, and parallel files are maintained, often */var/*/utmpx* and */var/*/wtmpx*.

Linux glibc on the other hand does not use a parallel *utmpx* file since its *utmp* structure is already large enough. The "x" functions listed above are just aliases for their counterparts without the "x" (e.g., **getutxent**() is an alias for *getutent*())

NOTES

glibc notes

The above functions are not thread-safe. glibc adds reentrant versions

#include <utmp.h>

int getutent_r(struct utmp ****ubuf*, struct utmp *****ubufp***);**
int getutid_r(struct utmp ****ut*,**
struct utmp ****ubuf*, struct utmp *****ubufp***);**
int getutline_r(struct utmp ****ut*,**
struct utmp ****ubuf*, struct utmp *****ubufp***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getutent_r(), **getutid_r**(), **getutline_r**():
_GNU_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

These functions are GNU extensions, analogs of the functions of the same name without the _r suffix. The *ubuf* argument gives these functions a place to store their result. On success, they return 0, and a pointer to the result is written in **ubufp*. On error, these functions return −1. There are no utmpx equivalents of the above functions. (POSIX.1 does not specify such functions.)

EXAMPLES

The following example adds and removes a utmp record, assuming it is run from within a pseudo terminal. For usage in a real application, you should check the return values of *getpwuid*(3) and *ttyname*(3).

```
#include <pwd.h>
#include <stdlib.h>
#include <string.h>
#include <time.h>
#include <unistd.h>
#include <utmp.h>

int
main(void)
{
    struct utmp entry;

    system("echo before adding entry:;who");

    entry.ut_type = USER_PROCESS;
    entry.ut_pid = getpid();
    strcpy(entry.ut_line, ttyname(STDIN_FILENO) + strlen("/dev/"));
    /* only correct for ptys named /dev/tty[pqr][0-9a-z] */
    strcpy(entry.ut_id, ttyname(STDIN_FILENO) + strlen("/dev/tty"));
    entry.ut_time = time(NULL);
    strcpy(entry.ut_user, getpwuid(getuid())->pw_name);
    memset(entry.ut_host, 0, UT_HOSTSIZE);
    entry.ut_addr = 0;
    setutent();
    pututline(&entry);

    system("echo after adding entry:;who");

    entry.ut_type = DEAD_PROCESS;
    memset(entry.ut_line, 0, UT_LINESIZE);
    entry.ut_time = 0;
    memset(entry.ut_user, 0, UT_NAMESIZE);
    setutent();
    pututline(&entry);

    system("echo after removing entry:;who");

    endutent();
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

getutmp(3), *utmp*(5)

NAME

getutmp, getutmpx − copy utmp structure to utmpx, and vice versa

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <utmpx.h>

void getutmp(const struct utmpx *ux, struct utmp *u);
void getutmpx(const struct utmp *u, struct utmpx *ux);
```

DESCRIPTION

The **getutmp**() function copies the fields of the *utmpx* structure pointed to by *ux* to the corresponding fields of the *utmp* structure pointed to by *u*. The **getutmpx**() function performs the converse operation.

RETURN VALUE

These functions do not return a value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getutmp(), **getutmpx**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

glibc 2.1.1. Solaris, NetBSD.

NOTES

These functions exist primarily for compatibility with other systems where the *utmp* and *utmpx* structures contain different fields, or the size of corresponding fields differs. On Linux, the two structures contain the same fields, and the fields have the same sizes.

SEE ALSO

utmpdump(1), *getutent*(3), *utmp*(5)

NAME

getw, putw − input and output of words (ints)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int getw(FILE *stream);
int putw(int w, FILE *stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

getw(), **putw**():
Since glibc 2.3.3:
_XOPEN_SOURCE && ! (_POSIX_C_SOURCE >= 200112L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
Before glibc 2.3.3:
_SVID_SOURCE || _BSD_SOURCE || _XOPEN_SOURCE

DESCRIPTION

getw() reads a word (that is, an *int*) from *stream*. It's provided for compatibility with SVr4. We recommend you use *fread*(3) instead.

putw() writes the word *w* (that is, an *int*) to *stream*. It is provided for compatibility with SVr4, but we recommend you use *fwrite*(3) instead.

RETURN VALUE

Normally, **getw**() returns the word read, and **putw**() returns 0. On error, they return **EOF**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getw(), **putw**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

SVr4, SUSv2.

BUGS

The value returned on error is also a legitimate data value. *ferror*(3) can be used to distinguish between the two cases.

SEE ALSO

ferror(3), *fread*(3), *fwrite*(3), *getc*(3), *putc*(3)

NAME

getwchar − read a wide character from standard input

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

wint_t getwchar(void);

DESCRIPTION

The **getwchar**() function is the wide-character equivalent of the *getchar*(3) function. It reads a wide character from *stdin* and returns it. If the end of stream is reached, or if *ferror(stdin)* becomes true, it returns **WEOF**. If a wide-character conversion error occurs, it sets *errno* to **EILSEQ** and returns **WEOF**.

For a nonlocking counterpart, see *unlocked_stdio*(3).

RETURN VALUE

The **getwchar**() function returns the next wide-character from standard input, or **WEOF**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
getwchar()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

NOTES

The behavior of **getwchar**() depends on the **LC_CTYPE** category of the current locale.

It is reasonable to expect that **getwchar**() will actually read a multibyte sequence from standard input and then convert it to a wide character.

SEE ALSO

fgetwc(3), *unlocked_stdio*(3)

NAME

glob, globfree − find pathnames matching a pattern, free memory from glob()

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <glob.h>

int glob(const char *restrict pattern, int flags,
    int (*errfunc)(const char *epath, int eerrno),
    glob_t *restrict pglob);
void globfree(glob_t *pglob);
```

DESCRIPTION

The **glob**() function searches for all the pathnames matching *pattern* according to the rules used by the shell (see *glob*(7)). No tilde expansion or parameter substitution is done; if you want these, use *wordexp*(3).

The **globfree**() function frees the dynamically allocated storage from an earlier call to **glob**().

The results of a **glob**() call are stored in the structure pointed to by *pglob*. This structure is of type *glob_t* (declared in <*glob.h*>) and includes the following elements defined by POSIX.2 (more may be present as an extension):

```
typedef struct {
    size_t   gl_pathc;    /* Count of paths matched so far  */
    char   **gl_pathv;    /* List of matched pathnames.  */
    size_t   gl_offs;     /* Slots to reserve in gl_pathv.  */
} glob_t;
```

Results are stored in dynamically allocated storage.

The argument *flags* is made up of the bitwise OR of zero or more the following symbolic constants, which modify the behavior of **glob**():

GLOB_ERR
: Return upon a read error (because a directory does not have read permission, for example). By default, **glob**() attempts carry on despite errors, reading all of the directories that it can.

GLOB_MARK
: Append a slash to each path which corresponds to a directory.

GLOB_NOSORT
: Don’t sort the returned pathnames. The only reason to do this is to save processing time. By default, the returned pathnames are sorted.

GLOB_DOOFFS
: Reserve *pglob−>gl_offs* slots at the beginning of the list of strings in *pglob−>pathv*. The reserved slots contain null pointers.

GLOB_NOCHECK
: If no pattern matches, return the original pattern. By default, **glob**() returns **GLOB_NOMATCH** if there are no matches.

GLOB_APPEND
: Append the results of this call to the vector of results returned by a previous call to **glob**(). Do not set this flag on the first invocation of **glob**().

GLOB_NOESCAPE
: Don’t allow backslash ('\') to be used as an escape character. Normally, a backslash can be used to quote the following character, providing a mechanism to turn off the special meaning metacharacters.

flags may also include any of the following, which are GNU extensions and not defined by POSIX.2:

GLOB_PERIOD
: Allow a leading period to be matched by metacharacters. By default, metacharacters can’t match a leading period.

GLOB_ALTDIRFUNC
Use alternative functions *pglob->gl_closedir*, *pglob->gl_readdir*, *pglob->gl_opendir*, *pglob->gl_lstat*, and *pglob->gl_stat* for filesystem access instead of the normal library functions.

GLOB_BRACE
Expand *csh*(1) style brace expressions of the form **{a,b}**. Brace expressions can be nested. Thus, for example, specifying the pattern "{foo/{,cat,dog},bar}" would return the same results as four separate **glob**() calls using the strings: "foo/", "foo/cat", "foo/dog", and "bar".

GLOB_NOMAGIC
If the pattern contains no metacharacters, then it should be returned as the sole matching word, even if there is no file with that name.

GLOB_TILDE
Carry out tilde expansion. If a tilde ('~') is the only character in the pattern, or an initial tilde is followed immediately by a slash ('/'), then the home directory of the caller is substituted for the tilde. If an initial tilde is followed by a username (e.g., "~andrea/bin"), then the tilde and username are substituted by the home directory of that user. If the username is invalid, or the home directory cannot be determined, then no substitution is performed.

GLOB_TILDE_CHECK
This provides behavior similar to that of **GLOB_TILDE**. The difference is that if the username is invalid, or the home directory cannot be determined, then instead of using the pattern itself as the name, **glob**() returns **GLOB_NOMATCH** to indicate an error.

GLOB_ONLYDIR
This is a *hint* to **glob**() that the caller is interested only in directories that match the pattern. If the implementation can easily determine file-type information, then nondirectory files are not returned to the caller. However, the caller must still check that returned files are directories. (The purpose of this flag is merely to optimize performance when the caller is interested only in directories.)

If *errfunc* is not NULL, it will be called in case of an error with the arguments *epath*, a pointer to the path which failed, and *eerrno*, the value of *errno* as returned from one of the calls to *opendir*(3), *readdir*(3), or *stat*(2). If *errfunc* returns nonzero, or if **GLOB_ERR** is set, **glob**() will terminate after the call to *errfunc*.

Upon successful return, *pglob->gl_pathc* contains the number of matched pathnames and *pglob->gl_pathv* contains a pointer to the list of pointers to matched pathnames. The list of pointers is terminated by a null pointer.

It is possible to call **glob**() several times. In that case, the **GLOB_APPEND** flag has to be set in *flags* on the second and later invocations.

As a GNU extension, *pglob->gl_flags* is set to the flags specified, **or**ed with **GLOB_MAGCHAR** if any metacharacters were found.

RETURN VALUE

On successful completion, **glob**() returns zero. Other possible returns are:

GLOB_NOSPACE
for running out of memory,

GLOB_ABORTED
for a read error, and

GLOB_NOMATCH
for no found matches.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
glob()	Thread safety	MT-Unsafe race:utent env sig:ALRM timer locale
globfree()	Thread safety	MT-Safe

In the above table, *utent* in *race:utent* signifies that if any of the functions *setutent*(3), *getutent*(3), or

endutent(3) are used in parallel in different threads of a program, then data races could occur. **glob**() calls those functions, so we use race:utent to remind users.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, POSIX.2.

NOTES

The structure elements *gl_pathc* and *gl_offs* are declared as *size_t* in glibc 2.1, as they should be according to POSIX.2, but are declared as *int* in glibc 2.0.

BUGS

The **glob**() function may fail due to failure of underlying function calls, such as *malloc*(3) or *opendir*(3). These will store their error code in *errno*.

EXAMPLES

One example of use is the following code, which simulates typing

```
ls -l *.c ../*.c
```

in the shell:

```
glob_t globbuf;

globbuf.gl_offs = 2;
glob("*.c", GLOB_DOOFFS, NULL, &globbuf);
glob("../*.c", GLOB_DOOFFS | GLOB_APPEND, NULL, &globbuf);
globbuf.gl_pathv[0] = "ls";
globbuf.gl_pathv[1] = "-l";
execvp("ls", &globbuf.gl_pathv[0]);
```

SEE ALSO

ls(1), *sh*(1), *stat*(2), *exec*(3), *fnmatch*(3), *malloc*(3), *opendir*(3), *readdir*(3), *wordexp*(3), *glob*(7)

NAME

gnu_get_libc_version, gnu_get_libc_release − get glibc version and release

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <gnu/libc-version.h>

const char *gnu_get_libc_version(void);
const char *gnu_get_libc_release(void);
```

DESCRIPTION

The function **gnu_get_libc_version**() returns a string that identifies the glibc version available on the system.

The function **gnu_get_libc_release**() returns a string indicates the release status of the glibc version available on the system. This will be a string such as *stable*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gnu_get_libc_version(), **gnu_get_libc_release**()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.1.

EXAMPLES

When run, the program below will produce output such as the following:

```
$ ./a.out
GNU libc version: 2.8
GNU libc release: stable
```

Program source

```
#include <stdio.h>
#include <stdlib.h>

#include <gnu/libc-version.h>

int
main(void)
{
    printf("GNU libc version: %s\n", gnu_get_libc_version());
    printf("GNU libc release: %s\n", gnu_get_libc_release());
    exit(EXIT_SUCCESS);
}
```

SEE ALSO

confstr(3)

NAME

grantpt − grant access to the slave pseudoterminal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int grantpt(int *fd***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

grantpt():
Since glibc 2.24:
_XOPEN_SOURCE >= 500
glibc 2.23 and earlier:
_XOPEN_SOURCE

DESCRIPTION

The **grantpt**() function changes the mode and owner of the slave pseudoterminal device corresponding to the master pseudoterminal referred to by the file descriptor *fd*. The user ID of the slave is set to the real UID of the calling process. The group ID is set to an unspecified value (e.g., *tty*). The mode of the slave is set to 0620 (crw−−w−−−−).

The behavior of **grantpt**() is unspecified if a signal handler is installed to catch **SIGCHLD** signals.

RETURN VALUE

When successful, **grantpt**() returns 0. Otherwise, it returns −1 and sets *errno* to indicate the error.

ERRORS

EACCES
The corresponding slave pseudoterminal could not be accessed.

EBADF
The *fd* argument is not a valid open file descriptor.

EINVAL
The *fd* argument is valid but not associated with a master pseudoterminal.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
grantpt()	Thread safety	MT-Safe locale

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

This is part of the UNIX 98 pseudoterminal support, see *pts*(4).

Historical systems implemented this function via a set-user-ID helper binary called "pt_chown". glibc on Linux before glibc 2.33 could do so as well, in order to support configurations with only BSD pseudoterminals; this support has been removed. On modern systems this is either a no-op —with permissions configured on pty allocation, as is the case on Linux— or an *ioctl*(2).

SEE ALSO

NAME

group_member − test whether a process is in a group

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int group_member(gid_t *gid***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

group_member():
_GNU_SOURCE

DESCRIPTION

The **group_member**() function tests whether any of the caller's supplementary group IDs (as returned by *getgroups*(2)) matches *gid*.

RETURN VALUE

The **group_member**() function returns nonzero if any of the caller's supplementary group IDs matches *gid*, and zero otherwise.

STANDARDS

GNU.

SEE ALSO

getgid(2), *getgroups*(2), *getgrouplist*(3), *group*(5)

NAME

gsignal, ssignal − software signal facility

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>

typedef void (*sighandler_t)(int);

[[deprecated]] int gsignal(int signum);

[[deprecated]] sighandler_t ssignal(int signum, sighandler_t action);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

gsignal(), **ssignal**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

Don't use these functions under Linux. Due to a historical mistake, under Linux these functions are aliases for *raise*(3) and *signal*(2), respectively.

Elsewhere, on System V-like systems, these functions implement software signaling, entirely independent of the classical *signal*(2) and *kill*(2) functions. The function **ssignal**() defines the action to take when the software signal with number *signum* is raised using the function **gsignal**(), and returns the previous such action or **SIG_DFL**. The function **gsignal**() does the following: if no action (or the action **SIG_DFL**) was specified for *signum*, then it does nothing and returns 0. If the action **SIG_IGN** was specified for *signum*, then it does nothing and returns 1. Otherwise, it resets the action to **SIG_DFL** and calls the action function with argument *signum*, and returns the value returned by that function. The range of possible values *signum* varies (often 1–15 or 1–17).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
gsignal()	Thread safety	MT-Safe
ssignal()	Thread safety	MT-Safe sigintr

STANDARDS

None.

HISTORY

AIX, DG/UX, HP-UX, SCO, Solaris, Tru64. They are called obsolete under most of these systems, and are broken under glibc. Some systems also have **gsignal_r**() and **ssignal_r**().

NAME

hash − hash database access method

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/types.h>
#include <db.h>

DESCRIPTION

Note well: This page documents interfaces provided up until glibc 2.1. Since glibc 2.2, glibc no longer provides these interfaces. Probably, you are looking for the APIs provided by the *libdb* library instead.

The routine *dbopen*(3) is the library interface to database files. One of the supported file formats is hash files. The general description of the database access methods is in *dbopen*(3), this manual page describes only the hash-specific information.

The hash data structure is an extensible, dynamic hashing scheme.

The access-method-specific data structure provided to *dbopen*(3) is defined in the <*db.h*> include file as follows:

```
typedef struct {
    unsigned int       bsize;
    unsigned int       ffactor;
    unsigned int       nelem;
    unsigned int       cachesize;
    uint32_t         (*hash)(const void *, size_t);
    int         lorder;
} HASHINFO;
```

The elements of this structure are as follows:

bsize defines the hash table bucket size, and is, by default, 256 bytes. It may be preferable to increase the page size for disk-resident tables and tables with large data items.

ffactor indicates a desired density within the hash table. It is an approximation of the number of keys allowed to accumulate in any one bucket, determining when the hash table grows or shrinks. The default value is 8.

nelem is an estimate of the final size of the hash table. If not set or set too low, hash tables will expand gracefully as keys are entered, although a slight performance degradation may be noticed. The default value is 1.

cachesize is the suggested maximum size, in bytes, of the memory cache. This value is *only advisory*, and the access method will allocate more memory rather than fail.

hash is a user-defined hash function. Since no hash function performs equally well on all possible data, the user may find that the built-in hash function does poorly on a particular data set. A user-specified hash functions must take two arguments (a pointer to a byte string and a length) and return a 32-bit quantity to be used as the hash value.

lorder is the byte order for integers in the stored database metadata. The number should represent the order as an integer; for example, big endian order would be the number 4,321. If *lorder* is 0 (no order is specified), the current host order is used. If the file already exists, the specified value is ignored and the value specified when the tree was created is used.

If the file already exists (and the **O_TRUNC** flag is not specified), the values specified for *bsize*, *ffactor*, *lorder*, and *nelem* are ignored and the values specified when the tree was created are used.

If a hash function is specified, *hash_open* attempts to determine if the hash function specified is the same as the one with which the database was created, and fails if it is not.

Backward-compatible interfaces to the routines described in *dbm*(3), and *ndbm*(3) are provided, however these interfaces are not compatible with previous file formats.

ERRORS

The *hash* access method routines may fail and set *errno* for any of the errors specified for the library routine *dbopen*(3).

BUGS

Only big and little endian byte order are supported.

NAME

hcreate, hdestroy, hsearch, hcreate_r, hdestroy_r, hsearch_r − hash table management

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <search.h>

int hcreate(size_t nel);
void hdestroy(void);

ENTRY *hsearch(ENTRY item, ACTION action);

#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <search.h>

int hcreate_r(size_t nel, struct hsearch_data *htab);
void hdestroy_r(struct hsearch_data *htab);

int hsearch_r(ENTRY item, ACTION action, ENTRY **retval,
        struct hsearch_data *htab);
```

DESCRIPTION

The three functions **hcreate**(), **hsearch**(), and **hdestroy**() allow the caller to create and manage a hash search table containing entries consisting of a key (a string) and associated data. Using these functions, only one hash table can be used at a time.

The three functions **hcreate_r**(), **hsearch_r**(), **hdestroy_r**() are reentrant versions that allow a program to use more than one hash search table at the same time. The last argument, *htab*, points to a structure that describes the table on which the function is to operate. The programmer should treat this structure as opaque (i.e., do not attempt to directly access or modify the fields in this structure).

First a hash table must be created using **hcreate**(). The argument *nel* specifies the maximum number of entries in the table. (This maximum cannot be changed later, so choose it wisely.) The implementation may adjust this value upward to improve the performance of the resulting hash table.

The **hcreate_r**() function performs the same task as **hcreate**(), but for the table described by the structure **htab*. The structure pointed to by *htab* must be zeroed before the first call to **hcreate_r**().

The function **hdestroy**() frees the memory occupied by the hash table that was created by **hcreate**(). After calling **hdestroy**(), a new hash table can be created using **hcreate**(). The **hdestroy_r**() function performs the analogous task for a hash table described by **htab*, which was previously created using **hcreate_r**().

The **hsearch**() function searches the hash table for an item with the same key as *item* (where "the same" is determined using *strcmp*(3)), and if successful returns a pointer to it.

The argument *item* is of type *ENTRY*, which is defined in <*search.h*> as follows:

```
typedef struct entry {
    char *key;
    void *data;
} ENTRY;
```

The field *key* points to a null-terminated string which is the search key. The field *data* points to data that is associated with that key.

The argument *action* determines what **hsearch**() does after an unsuccessful search. This argument must either have the value **ENTER**, meaning insert a copy of *item* (and return a pointer to the new hash table entry as the function result), or the value **FIND**, meaning that NULL should be returned. (If *action* is **FIND**, then *data* is ignored.)

The **hsearch_r**() function is like **hsearch**() but operates on the hash table described by **htab*. The **hsearch_r**() function differs from **hsearch**() in that a pointer to the found item is returned in **retval*, rather than as the function result.

RETURN VALUE

hcreate() and **hcreate_r**() return nonzero on success. They return 0 on error, with *errno* set to indicate the error.

On success, **hsearch**() returns a pointer to an entry in the hash table. **hsearch**() returns NULL on error, that is, if *action* is **ENTER** and the hash table is full, or *action* is **FIND** and *item* cannot be found in the hash table. **hsearch_r**() returns nonzero on success, and 0 on error. In the event of an error, these two functions set *errno* to indicate the error.

ERRORS

hcreate_r() and **hdestroy_r**() can fail for the following reasons:

EINVAL
htab is NULL.

hsearch() and **hsearch_r**() can fail for the following reasons:

ENOMEM
action was **ENTER**, *key* was not found in the table, and there was no room in the table to add a new entry.

ESRCH
action was **FIND**, and *key* was not found in the table.

POSIX.1 specifies only the **ENOMEM** error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
hcreate(), **hsearch**(), **hdestroy**()	Thread safety	MT-Unsafe race:hsearch
hcreate_r(), **hsearch_r**(), **hdestroy_r**()	Thread safety	MT-Safe race:htab

STANDARDS

hcreate()
hsearch()
hdestroy()
POSIX.1-2008.

hcreate_r()
hsearch_r()
hdestroy_r()
GNU.

HISTORY

hcreate()
hsearch()
hdestroy()
SVr4, POSIX.1-2001.

hcreate_r()
hsearch_r()
hdestroy_r()
GNU.

NOTES

Hash table implementations are usually more efficient when the table contains enough free space to minimize collisions. Typically, this means that *nel* should be at least 25% larger than the maximum number of elements that the caller expects to store in the table.

The **hdestroy**() and **hdestroy_r**() functions do not free the buffers pointed to by the *key* and *data* elements of the hash table entries. (It can't do this because it doesn't know whether these buffers were allocated dynamically.) If these buffers need to be freed (perhaps because the program is repeatedly creating and destroying hash tables, rather than creating a single table whose lifetime matches that of the program), then the program must maintain bookkeeping data structures that allow it to free them.

BUGS

SVr4 and POSIX.1-2001 specify that *action* is significant only for unsuccessful searches, so that an **ENTER** should not do anything for a successful search. In libc and glibc (before glibc 2.3), the implementation violates the specification, updating the *data* for the given *key* in this case.

Individual hash table entries can be added, but not deleted.

EXAMPLES

The following program inserts 24 items into a hash table, then prints some of them.

```
#include <search.h>
#include <stdio.h>
#include <stdlib.h>

static char *data[] = { "alpha", "bravo", "charlie", "delta",
     "echo", "foxtrot", "golf", "hotel", "india", "juliet",
     "kilo", "lima", "mike", "november", "oscar", "papa",
     "quebec", "romeo", "sierra", "tango", "uniform",
     "victor", "whisky", "x-ray", "yankee", "zulu"
};

int
main(void)
{
    ENTRY e;
    ENTRY *ep;

    hcreate(30);

    for (size_t i = 0; i < 24; i++) {
        e.key = data[i];
        /* data is just an integer, instead of a
           pointer to something */
        e.data = (void *) i;
        ep = hsearch(e, ENTER);
        /* there should be no failures */
        if (ep == NULL) {
            fprintf(stderr, "entry failed\n");
            exit(EXIT_FAILURE);
        }
    }

    for (size_t i = 22; i < 26; i++) {
        /* print two entries from the table, and
           show that two are not in the table */
        e.key = data[i];
        ep = hsearch(e, FIND);
        printf("%9.9s -> %9.9s:%d\n", e.key,
               ep ? ep->key : "NULL", ep ? (int)(ep->data) : 0);
    }
    hdestroy();
    exit(EXIT_SUCCESS);
}
```

NAME

hypot, hypotf, hypotl − Euclidean distance function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double hypot(double x, double y);
float hypotf(float x, float y);
long double hypotl(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

hypot():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

hypotf(), **hypotl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return sqrt(*x***x*+*y***y*). This is the length of the hypotenuse of a right-angled triangle with sides of length *x* and *y*, or the distance of the point (*x*,*y*) from the origin.

The calculation is performed without undue overflow or underflow during the intermediate steps of the calculation.

RETURN VALUE

On success, these functions return the length of the hypotenuse of a right-angled triangle with sides of length *x* and *y*.

If *x* or *y* is an infinity, positive infinity is returned.

If *x* or *y* is a NaN, and the other argument is not an infinity, a NaN is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively.

If both arguments are subnormal, and the result is subnormal, a range error occurs, and the correct result is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error: result underflow
: An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

  These functions do not set *errno* for this case.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

iconv − perform character set conversion

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <iconv.h>

size_t iconv(iconv_t cd,
             char **restrict inbuf, size_t *restrict inbytesleft,
             char **restrict outbuf, size_t *restrict outbytesleft);
```

DESCRIPTION

The **iconv**() function converts a sequence of characters in one character encoding to a sequence of characters in another character encoding. The *cd* argument is a conversion descriptor, previously created by a call to *iconv_open*(3); the conversion descriptor defines the character encodings that **iconv**() uses for the conversion. The *inbuf* argument is the address of a variable that points to the first character of the input sequence; *inbytesleft* indicates the number of bytes in that buffer. The *outbuf* argument is the address of a variable that points to the first byte available in the output buffer; *outbytesleft* indicates the number of bytes available in the output buffer.

The main case is when *inbuf* is not NULL and **inbuf* is not NULL. In this case, the **iconv**() function converts the multibyte sequence starting at **inbuf* to a multibyte sequence starting at **outbuf*. At most **inbytesleft* bytes, starting at **inbuf*, will be read. At most **outbytesleft* bytes, starting at **outbuf*, will be written.

The **iconv**() function converts one multibyte character at a time, and for each character conversion it increments **inbuf* and decrements **inbytesleft* by the number of converted input bytes, it increments **outbuf* and decrements **outbytesleft* by the number of converted output bytes, and it updates the conversion state contained in *cd*. If the character encoding of the input is stateful, the **iconv**() function can also convert a sequence of input bytes to an update to the conversion state without producing any output bytes; such input is called a *shift sequence*. The conversion can stop for five reasons:

- An invalid multibyte sequence is encountered in the input. In this case, it sets *errno* to **EILSEQ** and returns *(size_t) −1*. **inbuf* is left pointing to the beginning of the invalid multibyte sequence.
- A multibyte sequence is encountered that is valid but that cannot be translated to the character encoding of the output. This condition depends on the implementation and on the conversion descriptor. In the GNU C library and GNU libiconv, if *cd* was created without the suffix **//TRANSLIT** or **//IGNORE**, the conversion is strict: lossy conversions produce this condition. If the suffix **//TRANSLIT** was specified, transliteration can avoid this condition in some cases. In the musl C library, this condition cannot occur because a conversion to **'*'** is used as a fallback. In the FreeBSD, NetBSD, and Solaris implementations of **iconv**(), this condition cannot occur either, because a conversion to **'?'** is used as a fallback. When this condition is met, **iconv**() sets *errno* to **EILSEQ** and returns *(size_t) −1*. **inbuf* is left pointing to the beginning of the unconvertible multibyte sequence.
- The input byte sequence has been entirely converted, that is, **inbytesleft* has gone down to 0. In this case, **iconv**() returns the number of nonreversible conversions performed during this call.
- An incomplete multibyte sequence is encountered in the input, and the input byte sequence terminates after it. In this case, it sets *errno* to **EINVAL** and returns *(size_t) −1*. **inbuf* is left pointing to the beginning of the incomplete multibyte sequence.
- The output buffer has no more room for the next converted character. In this case, it sets *errno* to **E2BIG** and returns *(size_t) −1*.

A different case is when *inbuf* is NULL or **inbuf* is NULL, but *outbuf* is not NULL and **outbuf* is not NULL. In this case, the **iconv**() function attempts to set *cd*'s conversion state to the initial state and store a corresponding shift sequence at **outbuf*. At most **outbytesleft* bytes, starting at **outbuf*, will be written. If the output buffer has no more room for this reset sequence, it sets *errno* to **E2BIG** and returns *(size_t) −1*. Otherwise, it increments **outbuf* and decrements **outbytesleft* by the number of bytes written.

A third case is when *inbuf* is NULL or **inbuf* is NULL, and *outbuf* is NULL or **outbuf* is NULL. In

this case, the **iconv**() function sets *cd*'s conversion state to the initial state.

RETURN VALUE

The **iconv**() function returns the number of characters converted in a nonreversible way during this call; reversible conversions are not counted. In case of error, **iconv**() returns *(size_t) −1* and sets *errno* to indicate the error.

ERRORS

The following errors can occur, among others:

E2BIG There is not sufficient room at **outbuf*.

EILSEQ
An invalid multibyte sequence has been encountered in the input.

EINVAL
An incomplete multibyte sequence has been encountered in the input.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iconv()	Thread safety	MT-Safe race:cd

The **iconv**() function is MT-Safe, as long as callers arrange for mutual exclusion on the *cd* argument.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

NOTES

In each series of calls to **iconv**(), the last should be one with *inbuf* or **inbuf* equal to NULL, in order to flush out any partially converted input.

Although *inbuf* and *outbuf* are typed as *char* **, this does not mean that the objects they point can be interpreted as C strings or as arrays of characters: the interpretation of character byte sequences is handled internally by the conversion functions. In some encodings, a zero byte may be a valid part of a multibyte character.

The caller of **iconv**() must ensure that the pointers passed to the function are suitable for accessing characters in the appropriate character set. This includes ensuring correct alignment on platforms that have tight restrictions on alignment.

SEE ALSO

NAME

iconv_open − allocate descriptor for character set conversion

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <iconv.h>

iconv_t iconv_open(const char * *tocode***, const char *** *fromcode***);**

DESCRIPTION

The **iconv_open**() function allocates a conversion descriptor suitable for converting byte sequences from character encoding *fromcode* to character encoding *tocode*.

The values permitted for *fromcode* and *tocode* and the supported combinations are system-dependent. For the GNU C library, the permitted values are listed by the *iconv −−list* command, and all combinations of the listed values are supported. Furthermore the GNU C library and the GNU libiconv library support the following two suffixes:

//TRANSLIT
: When the string "//TRANSLIT" is appended to *tocode*, transliteration is activated. This means that when a character cannot be represented in the target character set, it can be approximated through one or several similarly looking characters.

//IGNORE
: When the string "//IGNORE" is appended to *tocode*, characters that cannot be represented in the target character set will be silently discarded.

The resulting conversion descriptor can be used with *iconv*(3) any number of times. It remains valid until deallocated using *iconv_close*(3).

A conversion descriptor contains a conversion state. After creation using **iconv_open**(), the state is in the initial state. Using *iconv*(3) modifies the descriptor's conversion state. To bring the state back to the initial state, use *iconv*(3) with NULL as *inbuf* argument.

RETURN VALUE

On success, **iconv_open**() returns a freshly allocated conversion descriptor. On failure, it returns *(iconv_t) −1* and sets *errno* to indicate the error.

ERRORS

The following error can occur, among others:

EINVAL
: The conversion from *fromcode* to *tocode* is not supported by the implementation.

NAME

if_nameindex, if_freenameindex − get network interface names and indexes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <net/if.h>

struct if_nameindex *if_nameindex(*void***);**
void if_freenameindex(struct if_nameindex ** *ptr*);**

DESCRIPTION

The **if_nameindex**() function returns an array of *if_nameindex* structures, each containing information about one of the network interfaces on the local system. The *if_nameindex* structure contains at least the following entries:

```
unsigned int if_index; /* Index of interface (1, 2, ...) */
char        *if_name;  /* Null-terminated name ("eth0", etc.) */
```

The *if_index* field contains the interface index. The *if_name* field points to the null-terminated interface name. The end of the array is indicated by entry with *if_index* set to zero and *if_name* set to NULL.

The data structure returned by **if_nameindex**() is dynamically allocated and should be freed using **if_freenameindex**() when no longer needed.

RETURN VALUE

On success, **if_nameindex**() returns pointer to the array; on error, NULL is returned, and *errno* is set to indicate the error.

ERRORS

if_nameindex() may fail and set *errno* if:

ENOBUFS
Insufficient resources available.

if_nameindex() may also fail for any of the errors specified for *socket*(2), *bind*(2), *ioctl*(2), *getsockname*(2), *recvmsg*(2), *sendto*(2), or *malloc*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
if_nameindex(), **if_freenameindex**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008, RFC 3493.

HISTORY

glibc 2.1. POSIX.1-2001. BSDi.

Before glibc 2.3.4, the implementation supported only interfaces with IPv4 addresses. Support of interfaces that don't have IPv4 addresses is available only on kernels that support netlink.

EXAMPLES

The program below demonstrates the use of the functions described on this page. An example of the output this program might produce is the following:

```
$ ./a.out
1: lo
2: wlan0
3: em1
```

Program source

```
#include <net/if.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
```

```
main(void)
{
    struct if_nameindex *if_ni, *i;

    if_ni = if_nameindex();
    if (if_ni == NULL) {
        perror("if_nameindex");
        exit(EXIT_FAILURE);
    }

    for (i = if_ni; !(i->if_index == 0 && i->if_name == NULL); i++)
        printf("%u: %s\n", i->if_index, i->if_name);

    if_freenameindex(if_ni);

    exit(EXIT_SUCCESS);
}
```

NAME

if_nametoindex, if_indextoname − mappings between network interface names and indexes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <net/if.h>

unsigned int if_nametoindex(const char *ifname);
char *if_indextoname(unsigned int ifindex, char *ifname);
```

DESCRIPTION

The **if_nametoindex**() function returns the index of the network interface corresponding to the name *ifname*.

The **if_indextoname**() function returns the name of the network interface corresponding to the interface index *ifindex*. The name is placed in the buffer pointed to by *ifname*. The buffer must allow for the storage of at least **IF_NAMESIZE** bytes.

RETURN VALUE

On success, **if_nametoindex**() returns the index number of the network interface; on error, 0 is returned and *errno* is set to indicate the error.

On success, **if_indextoname**() returns *ifname*; on error, NULL is returned and *errno* is set to indicate the error.

ERRORS

if_nametoindex() may fail and set *errno* if:

ENODEV
No interface found with given name.

if_indextoname() may fail and set *errno* if:

ENXIO
No interface found for the index.

if_nametoindex() and **if_indextoname**() may also fail for any of the errors specified for *socket*(2) or *ioctl*(2).

ilogb, ilogbf, ilogbl − get integer exponent of a floating-point value

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

int ilogb(double x);
int ilogbf(float x);
int ilogbl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ilogb():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

ilogbf(), **ilogbl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the exponent part of their argument as a signed integer. When no error occurs, these functions are equivalent to the corresponding *logb*(3) functions, cast to *int*.

RETURN VALUE

On success, these functions return the exponent of *x*, as a signed integer.

If *x* is zero, then a domain error occurs, and the functions return **FP_ILOGB0**.

If *x* is a NaN, then a domain error occurs, and the functions return **FP_ILOGBNAN**.

If *x* is negative infinity or positive infinity, then a domain error occurs, and the functions return **INT_MAX**.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is 0 or a NaN
: An invalid floating-point exception (**FE_INVALID**) is raised, and *errno* is set to **EDOM** (but see BUGS).

Domain error: *x* is an infinity
: An invalid floating-point exception (**FE_INVALID**) is raised, and *errno* is set to **EDOM** (but see BUGS).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ilogb(), **ilogbf**(), **ilogbl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

BUGS

Before glibc 2.16, the following bugs existed in the glibc implementation of these functions:

- The domain error case where *x* is 0 or a NaN did not cause *errno* to be set or (on some architectures) raise a floating-point exception.
- The domain error case where *x* is an infinity did not cause *errno* to be set or raise a floating-point exception.

NAME

index, rindex − locate character in string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <strings.h>

[[deprecated]] char *index(const char *s, int c);
[[deprecated]] char *rindex(const char *s, int c);
```

DESCRIPTION

index() is identical to *strchr*(3).

rindex() is identical to *strrchr*(3).

Use *strchr*(3) and *strrchr*(3) instead of these functions.

STANDARDS

None.

HISTORY

4.3BSD; marked as LEGACY in POSIX.1-2001. Removed in POSIX.1-2008, recommending *strchr*(3) and *strrchr*(3) instead.

SEE ALSO

NAME

inet_aton, inet_addr, inet_network, inet_ntoa, inet_makeaddr, inet_lnaof, inet_netof − Internet address manipulation routines

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>

int inet_aton(const char *cp, struct in_addr *inp);

in_addr_t inet_addr(const char *cp);
in_addr_t inet_network(const char *cp);

[[deprecated]] char *inet_ntoa(struct in_addr in);

[[deprecated]] struct in_addr inet_makeaddr(in_addr_t net,
                                            in_addr_t host);

[[deprecated]] in_addr_t inet_lnaof(struct in_addr in);
[[deprecated]] in_addr_t inet_netof(struct in_addr in);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

inet_aton(), **inet_ntoa**():
Since glibc 2.19:
_DEFAULT_SOURCE
In glibc up to and including 2.19:
_BSD_SOURCE || _BSD_SOURCE

DESCRIPTION

inet_aton() converts the Internet host address *cp* from the IPv4 numbers-and-dots notation into binary form (in network byte order) and stores it in the structure that *inp* points to. **inet_aton**() returns nonzero if the address is valid, zero if not. The address supplied in *cp* can have one of the following forms:

a.b.c.d Each of the four numeric parts specifies a byte of the address; the bytes are assigned in left-to-right order to produce the binary address.

a.b.c Parts *a* and *b* specify the first two bytes of the binary address. Part *c* is interpreted as a 16-bit value that defines the rightmost two bytes of the binary address. This notation is suitable for specifying (outmoded) Class B network addresses.

a.b Part *a* specifies the first byte of the binary address. Part *b* is interpreted as a 24-bit value that defines the rightmost three bytes of the binary address. This notation is suitable for specifying (outmoded) Class A network addresses.

a The value *a* is interpreted as a 32-bit value that is stored directly into the binary address without any byte rearrangement.

In all of the above forms, components of the dotted address can be specified in decimal, octal (with a leading *0*), or hexadecimal, with a leading *0X*). Addresses in any of these forms are collectively termed *IPV4 numbers-and-dots notation*. The form that uses exactly four decimal numbers is referred to as *IPv4 dotted-decimal notation* (or sometimes: *IPv4 dotted-quad notation*).

inet_aton() returns 1 if the supplied string was successfully interpreted, or 0 if the string is invalid (**errno** is *not* set on error).

The **inet_addr**() function converts the Internet host address *cp* from IPv4 numbers-and-dots notation into binary data in network byte order. If the input is invalid, **INADDR_NONE** (usually −1) is returned. Use of this function is problematic because −1 is a valid address (255.255.255.255). Avoid its use in favor of **inet_aton**(), *inet_pton*(3), or *getaddrinfo*(3), which provide a cleaner way to indicate error return.

The **inet_network**() function converts *cp*, a string in IPv4 numbers-and-dots notation, into a number in host byte order suitable for use as an Internet network address. On success, the converted address is

returned. If the input is invalid, −1 is returned.

The **inet_ntoa**() function converts the Internet host address *in*, given in network byte order, to a string in IPv4 dotted-decimal notation. The string is returned in a statically allocated buffer, which subsequent calls will overwrite.

The **inet_lnaof**() function returns the local network address part of the Internet address *in*. The returned value is in host byte order.

The **inet_netof**() function returns the network number part of the Internet address *in*. The returned value is in host byte order.

The **inet_makeaddr**() function is the converse of **inet_netof**() and **inet_lnaof**(). It returns an Internet host address in network byte order, created by combining the network number *net* with the local address *host*, both in host byte order.

The structure *in_addr* as used in **inet_ntoa**(), **inet_makeaddr**(), **inet_lnaof**(), and **inet_netof**() is defined in <*netinet/in.h*> as:

```
typedef uint32_t in_addr_t;

struct in_addr {
    in_addr_t s_addr;
};
```

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
inet_aton(), **inet_addr**(), **inet_network**(), **inet_ntoa**()	Thread safety	MT-Safe locale
inet_makeaddr(), **inet_lnaof**(), **inet_netof**()	Thread safety	MT-Safe

STANDARDS

inet_addr()
inet_ntoa()
: POSIX.1-2008.

inet_aton()
: None.

STANDARDS

inet_addr()
inet_ntoa()
: POSIX.1-2001, 4.3BSD.

inet_lnaof(), **inet_netof**(), and **inet_makeaddr**() are legacy functions that assume they are dealing with *classful network addresses*. Classful networking divides IPv4 network addresses into host and network components at byte boundaries, as follows:

Class A
: This address type is indicated by the value 0 in the most significant bit of the (network byte ordered) address. The network address is contained in the most significant byte, and the host address occupies the remaining three bytes.

Class B
: This address type is indicated by the binary value 10 in the most significant two bits of the address. The network address is contained in the two most significant bytes, and the host address occupies the remaining two bytes.

Class C
: This address type is indicated by the binary value 110 in the most significant three bits of the address. The network address is contained in the three most significant bytes, and the host address occupies the remaining byte.

Classful network addresses are now obsolete, having been superseded by Classless Inter-Domain Routing (CIDR), which divides addresses into network and host components at arbitrary bit (rather than byte) boundaries.

NOTES

On x86 architectures, the host byte order is Least Significant Byte first (little endian), whereas the network byte order, as used on the Internet, is Most Significant Byte first (big endian).

EXAMPLES

An example of the use of **inet_aton**() and **inet_ntoa**() is shown below. Here are some example runs:

```
$ ./a.out 226.000.000.037      # Last byte is in octal
226.0.0.31
$ ./a.out 0x7f.1               # First byte is in hex
127.0.0.1
```

Program source

```
#define _DEFAULT_SOURCE
#include <arpa/inet.h>
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
{
    struct in_addr addr;

    if (argc != 2) {
        fprintf(stderr, "%s <dotted-address>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    if (inet_aton(argv[1], &addr) == 0) {
        fprintf(stderr, "Invalid address\n");
        exit(EXIT_FAILURE);
    }

    printf("%s\n", inet_ntoa(addr));
    exit(EXIT_SUCCESS);
}
```

NAME

inet_net_pton, inet_net_ntop − Internet network number conversion

LIBRARY

Resolver library (*libresolv*, *−lresolv*)

SYNOPSIS

```
#include <arpa/inet.h>

int inet_net_pton(int af, const char *pres,
                  void netp[.nsize], size_t nsize);
char *inet_net_ntop(int af,
                  const void netp[(.bits - CHAR_BIT + 1) / CHAR_BIT],
                  int bits,
                  char  pres[.psize], size_t  psize);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

inet_net_pton(), **inet_net_ntop**():
Since glibc 2.20:
_DEFAULT_SOURCE
Before glibc 2.20:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions convert network numbers between presentation (i.e., printable) format and network (i.e., binary) format.

For both functions, *af* specifies the address family for the conversion; the only supported value is **AF_INET**.

inet_net_pton()

The **inet_net_pton**() function converts *pres*, a null-terminated string containing an Internet network number in presentation format to network format. The result of the conversion, which is in network byte order, is placed in the buffer pointed to by *netp*. (The *netp* argument typically points to an *in_addr* structure.) The *nsize* argument specifies the number of bytes available in *netp*.

On success, **inet_net_pton**() returns the number of bits in the network number field of the result placed in *netp*. For a discussion of the input presentation format and the return value, see NOTES.

Note: the buffer pointed to by *netp* should be zeroed out before calling **inet_net_pton**(), since the call writes only as many bytes as are required for the network number (or as are explicitly specified by *pres*), which may be less than the number of bytes in a complete network address.

inet_net_ntop()

The **inet_net_ntop**() function converts the network number in the buffer pointed to by *netp* to presentation format; **netp* is interpreted as a value in network byte order. The *bits* argument specifies the number of bits in the network number in **netp*.

The null-terminated presentation-format string is placed in the buffer pointed to by *pres*. The *psize* argument specifies the number of bytes available in *pres*. The presentation string is in CIDR format: a dotted-decimal number representing the network address, followed by a slash, and the size of the network number in bits.

RETURN VALUE

On success, **inet_net_pton**() returns the number of bits in the network number. On error, it returns −1, and *errno* is set to indicate the error.

On success, **inet_net_ntop**() returns *pres*. On error, it returns NULL, and *errno* is set to indicate the error.

ERRORS

EAFNOSUPPORT
af specified a value other than **AF_INET**.

EMSGSIZE
The size of the output buffer was insufficient.

ENOENT
(**inet_net_pton**()) *pres* was not in correct presentation format.

STANDARDS

None.

NOTES

Input presentation format for inet_net_pton()

The network number may be specified either as a hexadecimal value or in dotted-decimal notation.

Hexadecimal values are indicated by an initial "0x" or "0X". The hexadecimal digits populate the nibbles (half octets) of the network number from left to right in network byte order.

In dotted-decimal notation, up to four octets are specified, as decimal numbers separated by dots. Thus, any of the following forms are accepted:

```
a.b.c.d
a.b.c
a.b
a
```

Each part is a number in the range 0 to 255 that populates one byte of the resulting network number, going from left to right, in network-byte (big endian) order. Where a part is omitted, the resulting byte in the network number is zero.

For either hexadecimal or dotted-decimal format, the network number can optionally be followed by a slash and a number in the range 0 to 32, which specifies the size of the network number in bits.

Return value of inet_net_pton()

The return value of **inet_net_pton**() is the number of bits in the network number field. If the input presentation string terminates with a slash and an explicit size value, then that size becomes the return value of **inet_net_pton**(). Otherwise, the return value, *bits*, is inferred as follows:

- If the most significant byte of the network number is greater than or equal to 240, then *bits* is 32.
- Otherwise, if the most significant byte of the network number is greater than or equal to 224, then *bits* is 4.
- Otherwise, if the most significant byte of the network number is greater than or equal to 192, then *bits* is 24.
- Otherwise, if the most significant byte of the network number is greater than or equal to 128, then *bits* is 16.
- Otherwise, *bits* is 8.

If the resulting *bits* value from the above steps is greater than or equal to 8, but the number of octets specified in the network number exceed *bits/8*, then *bits* is set to 8 times the number of octets actually specified.

EXAMPLES

The program below demonstrates the use of **inet_net_pton**() and **inet_net_ntop**(). It uses **inet_net_pton**() to convert the presentation format network address provided in its first command-line argument to binary form, displays the return value from **inet_net_pton**(). It then uses **inet_net_ntop**() to convert the binary form back to presentation format, and displays the resulting string.

In order to demonstrate that **inet_net_pton**() may not write to all bytes of its *netp* argument, the program allows an optional second command-line argument, a number used to initialize the buffer before **inet_net_pton**() is called. As its final line of output, the program displays all of the bytes of the buffer returned by **inet_net_pton**() allowing the user to see which bytes have not been touched by **inet_net_pton**().

An example run, showing that **inet_net_pton**() infers the number of bits in the network number:

```
$ ./a.out 193.168
inet_net_pton() returned: 24
inet_net_ntop() yielded:  193.168.0/24
Raw address:              c1a80000
```

Demonstrate that **inet_net_pton**() does not zero out unused bytes in its result buffer:

```
$ ./a.out 193.168 0xffffffff
inet_net_pton() returned: 24
inet_net_ntop() yielded:  193.168.0/24
Raw address:              c1a800ff
```

Demonstrate that **inet_net_pton**() will widen the inferred size of the network number, if the supplied number of bytes in the presentation string exceeds the inferred value:

```
$ ./a.out 193.168.1.128
inet_net_pton() returned: 32
inet_net_ntop() yielded:  193.168.1.128/32
Raw address:              c1a80180
```

Explicitly specifying the size of the network number overrides any inference about its size (but any extra bytes that are explicitly specified will still be used by **inet_net_pton**(): to populate the result buffer):

```
$ ./a.out 193.168.1.128/24
inet_net_pton() returned: 24
inet_net_ntop() yielded:  193.168.1/24
Raw address:              c1a80180
```

    }
```

SEE ALSO

inet(3), *networks*(5)

NAME

inet_ntop − convert IPv4 and IPv6 addresses from binary to text form

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <arpa/inet.h>

const char *inet_ntop(int af, const void *restrict src,
                      char dst[restrict .size], socklen_t size);
```

DESCRIPTION

This function converts the network address structure *src* in the *af* address family into a character string. The resulting string is copied to the buffer pointed to by *dst*, which must be a non-null pointer. The caller specifies the number of bytes available in this buffer in the argument *size*.

inet_ntop() extends the *inet_ntoa*(3) function to support multiple address families, *inet_ntoa*(3) is now considered to be deprecated in favor of **inet_ntop**(). The following address families are currently supported:

AF_INET
: *src* points to a *struct in_addr* (in network byte order) which is converted to an IPv4 network address in the dotted-decimal format, "*ddd.ddd.ddd.ddd*". The buffer *dst* must be at least **INET_ADDRSTRLEN** bytes long.

AF_INET6
: *src* points to a *struct in6_addr* (in network byte order) which is converted to a representation of this address in the most appropriate IPv6 network address format for this address. The buffer *dst* must be at least **INET6_ADDRSTRLEN** bytes long.

RETURN VALUE

On success, **inet_ntop**() returns a non-null pointer to *dst*. NULL is returned if there was an error, with *errno* set to indicate the error.

ERRORS

EAFNOSUPPORT
: *af* was not a valid address family.

ENOSPC
: The converted address string would exceed the size given by *size*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
inet_ntop()	Thread safety	MT-Safe locale

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

Note that RFC 2553 defines a prototype where the last argument *size* is of type *size_t*. Many systems follow RFC 2553. glibc 2.0 and 2.1 have *size_t*, but 2.2 and later have *socklen_t*.

BUGS

AF_INET6 converts IPv4-mapped IPv6 addresses into an IPv6 format.

EXAMPLES

See *inet_pton*(3).

SEE ALSO

getnameinfo(3), *inet*(3), *inet_pton*(3)

NAME

inet_pton − convert IPv4 and IPv6 addresses from text to binary form

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <arpa/inet.h>

int inet_pton(int *af***, const char *restrict** *src***, void *restrict** *dst***);**

DESCRIPTION

This function converts the character string *src* into a network address structure in the *af* address family, then copies the network address structure to *dst*. The *af* argument must be either **AF_INET** or **AF_INET6**. *dst* is written in network byte order.

The following address families are currently supported:

AF_INET

src points to a character string containing an IPv4 network address in dotted-decimal format, "*ddd.ddd.ddd.ddd*", where *ddd* is a decimal number of up to three digits in the range 0 to 255. The address is converted to a *struct in_addr* and copied to *dst*, which must be *sizeof(struct in_addr)* (4) bytes (32 bits) long.

AF_INET6

src points to a character string containing an IPv6 network address. The address is converted to a *struct in6_addr* and copied to *dst*, which must be *sizeof(struct in6_addr)* (16) bytes (128 bits) long. The allowed formats for IPv6 addresses follow these rules:

- The preferred format is *x:x:x:x:x:x:x:x*. This form consists of eight hexadecimal numbers, each of which expresses a 16-bit value (i.e., each *x* can be up to 4 hex digits).
- A series of contiguous zero values in the preferred format can be abbreviated to *::*. Only one instance of *::* can occur in an address. For example, the loopback address *0:0:0:0:0:0:0:1* can be abbreviated as *::1*. The wildcard address, consisting of all zeros, can be written as *::*.
- An alternate format is useful for expressing IPv4-mapped IPv6 addresses. This form is written as *x:x:x:x:x:x:d.d.d.d*, where the six leading *x*s are hexadecimal values that define the six most-significant 16-bit pieces of the address (i.e., 96 bits), and the *d*s express a value in dotted-decimal notation that defines the least significant 32 bits of the address. An example of such an address is *::FFFF:204.152.189.116*.

See RFC 2373 for further details on the representation of IPv6 addresses.

RETURN VALUE

inet_pton() returns 1 on success (network address was successfully converted). 0 is returned if *src* does not contain a character string representing a valid network address in the specified address family. If *af* does not contain a valid address family, −1 is returned and *errno* is set to **EAFNOSUPPORT**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
inet_pton()	Thread safety	MT-Safe locale

VERSIONS

Unlike *inet_aton*(3) and *inet_addr*(3), **inet_pton**() supports IPv6 addresses. On the other hand, **inet_pton**() accepts only IPv4 addresses in dotted-decimal notation, whereas *inet_aton*(3) and *inet_addr*(3) allow the more general numbers-and-dots notation (hexadecimal and octal number formats, and formats that don't require all four bytes to be explicitly written). For an interface that handles both IPv6 addresses, and IPv4 addresses in numbers-and-dots notation, see *getaddrinfo*(3).

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

BUGS

AF_INET6 does not recognize IPv4 addresses. An explicit IPv4-mapped IPv6 address must be supplied in *src* instead.

EXAMPLES

The program below demonstrates the use of **inet_pton**() and *inet_ntop*(3). Here are some example runs:

```
$ ./a.out i6 0:0:0:0:0:0:0:0
::
$ ./a.out i6 1:0:0:0:0:0:0:8
1::8
$ ./a.out i6 0:0:0:0:0:FFFF:204.152.189.116
::ffff:204.152.189.116
```

Program source

```
#include <arpa/inet.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(int argc, char *argv[])
{
    unsigned char buf[sizeof(struct in6_addr)];
    int domain, s;
    char str[INET6_ADDRSTRLEN];

    if (argc != 3) {
        fprintf(stderr, "Usage: %s {i4|i6|<num>} string\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    domain = (strcmp(argv[1], "i4") == 0) ? AF_INET :
             (strcmp(argv[1], "i6") == 0) ? AF_INET6 : atoi(argv[1]);

    s = inet_pton(domain, argv[2], buf);
    if (s <= 0) {
        if (s == 0)
            fprintf(stderr, "Not in presentation format");
        else
            perror("inet_pton");
        exit(EXIT_FAILURE);
    }

    if (inet_ntop(domain, buf, str, INET6_ADDRSTRLEN) == NULL) {
        perror("inet_ntop");
        exit(EXIT_FAILURE);
    }

    printf("%s\n", str);

    exit(EXIT_SUCCESS);
}
```

NAME

INFINITY, NAN, HUGE_VAL, HUGE_VALF, HUGE_VALL − floating-point constants

LIBRARY

Math library (*libm*)

SYNOPSIS

```
#define _ISOC99_SOURCE      /* See feature_test_macros(7) */
#include <math.h>

INFINITY

NAN

HUGE_VAL
HUGE_VALF
HUGE_VALL
```

DESCRIPTION

The macro **INFINITY** expands to a *float* constant representing positive infinity.

The macro **NAN** expands to a *float* constant representing a quiet NaN (when supported). A *quiet* NaN is a NaN ("not-a-number") that does not raise exceptions when it is used in arithmetic. The opposite is a *signaling* NaN. See IEC 60559:1989.

The macros **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL** expand to constants of types *double*, *float*, and *long double*, respectively, that represent a large positive value, possibly positive infinity.

STANDARDS

C11.

HISTORY

C99.

On a glibc system, the macro **HUGE_VAL** is always available. Availability of the **NAN** macro can be tested using **#ifdef NAN**, and similarly for **INFINITY**, **HUGE_VALF**, **HUGE_VALL**. They will be defined by <*math.h*> if **_ISOC99_SOURCE** or **_GNU_SOURCE** is defined, or **__STDC_VERSION__** is defined and has a value not less than 199901L.

NAME

initgroups − initialize the supplementary group access list

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <grp.h>

int initgroups(const char *user, gid_t group);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

initgroups():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The **initgroups**() function initializes the group access list by reading the group database */etc/group* and using all groups of which *user* is a member. The additional group *group* is also added to the list.

The *user* argument must be non-NULL.

RETURN VALUE

The **initgroups**() function returns 0 on success. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

ENOMEM
Insufficient memory to allocate group information structure.

EPERM
The calling process has insufficient privilege. See the underlying system call *setgroups*(2).

FILES

/etc/group
group database file

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
initgroups()	Thread safety	MT-Safe locale

STANDARDS

None.

HISTORY

NAME

insque, remque − insert/remove an item from a queue

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <search.h>

void insque(void ****elem*, void ****prev***);**
void remque(void ****elem*);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

insque(), **remque**():
_XOPEN_SOURCE >= 500
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE

DESCRIPTION

The **insque**() and **remque**() functions manipulate doubly linked lists. Each element in the list is a structure of which the first two elements are a forward and a backward pointer. The linked list may be linear (i.e., NULL forward pointer at the end of the list and NULL backward pointer at the start of the list) or circular.

The **insque**() function inserts the element pointed to by *elem* immediately after the element pointed to by *prev*.

If the list is linear, then the call *insque(elem, NULL)* can be used to insert the initial list element, and the call sets the forward and backward pointers of *elem* to NULL.

If the list is circular, the caller should ensure that the forward and backward pointers of the first element are initialized to point to that element, and the *prev* argument of the **insque**() call should also point to the element.

The **remque**() function removes the element pointed to by *elem* from the doubly linked list.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
insque(), **remque**()	Thread safety	MT-Safe

VERSIONS

On ancient systems, the arguments of these functions were of type *struct qelem* *, defined as:

```
struct qelem {
    struct qelem *q_forw;
    struct qelem *q_back;
    char          q_data[1];
};
```

This is still what you will get if **_GNU_SOURCE** is defined before including <*search.h*>.

The location of the prototypes for these functions differs among several versions of UNIX. The above is the POSIX version. Some systems place them in <*string.h*>.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

BUGS

In glibc 2.4 and earlier, it was not possible to specify *prev* as NULL. Consequently, to build a linear list, the caller had to build a list using an initial call that contained the first two elements of the list, with the forward and backward pointers in each element suitably initialized.

EXAMPLES

The program below demonstrates the use of **insque**(). Here is an example run of the program:

```
$ ./a.out -c a b c
Traversing completed list:
    a
    b
    c
That was a circular list
```

Program source

```
#include <search.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

struct element {
    struct element *forward;
    struct element *backward;
    char *name;
};

static struct element *
new_element(void)
{
    struct element *e;

    e = malloc(sizeof(*e));
    if (e == NULL) {
        fprintf(stderr, "malloc() failed\n");
        exit(EXIT_FAILURE);
    }

    return e;
}

int
main(int argc, char *argv[])
{
    struct element *first, *elem, *prev;
    int circular, opt, errfnd;

    /* The "-c" command-line option can be used to specify that the
       list is circular. */

    errfnd = 0;
    circular = 0;
    while ((opt = getopt(argc, argv, "c")) != -1) {
        switch (opt) {
        case 'c':
            circular = 1;
            break;
        default:
            errfnd = 1;
            break;
        }
    }

    if (errfnd || optind >= argc) {
        fprintf(stderr,  "Usage: %s [-c] string...\n", argv[0]);
        exit(EXIT_FAILURE);
```

```
        }

        /* Create first element and place it in the linked list. */

        elem = new_element();
        first = elem;

        elem->name = argv[optind];

        if (circular) {
            elem->forward = elem;
            elem->backward = elem;
            insque(elem, elem);
        } else {
            insque(elem, NULL);
        }

        /* Add remaining command-line arguments as list elements. */

        while (++optind < argc) {
            prev = elem;

            elem = new_element();
            elem->name = argv[optind];
            insque(elem, prev);
        }

        /* Traverse the list from the start, printing element names. */

        printf("Traversing completed list:\n");
        elem = first;
        do {
            printf("    %s\n", elem->name);
            elem = elem->forward;
        } while (elem != NULL && elem != first);

        if (elem == first)
            printf("That was a circular list\n");

        exit(EXIT_SUCCESS);
    }
```

  Before glibc 2.10:
    _GNU_SOURCE

DESCRIPTION

These functions check whether *c*, which must have the value of an *unsigned char* or **EOF**, falls into a certain character class according to the specified locale. The functions without the "_l" suffix perform the check based on the current locale.

The functions with the "_l" suffix perform the check based on the locale specified by the locale object *locale*. The behavior of these functions is undefined if *locale* is the special locale object **LC_GLOBAL_LOCALE** (see *duplocale*(3)) or is not a valid locale object handle.

The list below explains the operation of the functions without the "_l" suffix; the functions with the "_l" suffix differ only in using the locale object *locale* instead of the current locale.

isalnum()
: checks for an alphanumeric character; it is equivalent to **(isalpha(***c***) || isdigit(***c***))**.

isalpha()
: checks for an alphabetic character; in the standard **"C"** locale, it is equivalent to **(isupper(***c***) || islower(***c***))**. In some locales, there may be additional characters for which **isalpha**() is true—letters which are neither uppercase nor lowercase.

isascii()
: checks whether *c* is a 7-bit *unsigned char* value that fits into the ASCII character set.

isblank()
: checks for a blank character; that is, a space or a tab.

iscntrl()
: checks for a control character.

isdigit()
: checks for a digit (0 through 9).

isgraph()
: checks for any printable character except space.

islower()
: checks for a lowercase character.

isprint()
: checks for any printable character including space.

ispunct()
: checks for any printable character which is not a space or an alphanumeric character.

isspace()
: checks for white-space characters. In the **"C"** and **"POSIX"** locales, these are: space, form-feed (**'\f'**), newline (**'\n'**), carriage return (**'\r'**), horizontal tab (**'\t'**), and vertical tab (**'\v'**).

isupper()
: checks for an uppercase letter.

isxdigit()
: checks for hexadecimal digits, that is, one of
0 1 2 3 4 5 6 7 8 9 a b c d e f A B C D E F.

RETURN VALUE

The values returned are nonzero if the character *c* falls into the tested class, and zero if not.

glibc 2.3. POSIX.1-2008.

isascii_l()
glibc 2.3.

CAVEATS

The standards require that the argument *c* for these functions is either **EOF** or a value that is representable in the type *unsigned char*; otherwise, the behavior is undefined. If the argument *c* is of type *char*, it must be cast to *unsigned char*, as in the following example:

```
char c;
...
res = toupper((unsigned char) c);
```

This is necessary because *char* may be the equivalent of *signed char*, in which case a byte where the top bit is set would be sign extended when converting to *int*, yielding a value that is outside the range of *unsigned char*.

The details of what characters belong to which class depend on the locale. For example, **isupper**() will not recognize an A-umlaut (Ä) as an uppercase letter in the default **C** locale.

NAME

isatty − test whether a file descriptor refers to a terminal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int isatty(int *fd***);**

DESCRIPTION

The **isatty**() function tests whether *fd* is an open file descriptor referring to a terminal.

RETURN VALUE

isatty() returns 1 if *fd* is an open file descriptor referring to a terminal; otherwise 0 is returned, and *errno* is set to indicate the error.

ERRORS

EBADF

fd is not a valid file descriptor.

ENOTTY

fd refers to a file other than a terminal. On some older kernels, some types of files resulted in the error **EINVAL** in this case (which is a violation of POSIX, which specifies the error **ENOTTY**).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
isatty()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

SEE ALSO

fstat(2), *ttyname*(3)

NAME

isfdtype − test file type of a file descriptor

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/stat.h>
#include <sys/socket.h>

int isfdtype(int *fd***, int** *fdtype***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

isfdtype():
Since glibc 2.20:
_DEFAULT_SOURCE
Before glibc 2.20:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **isfdtype**() function tests whether the file descriptor *fd* refers to a file of type *fdtype*. The *fdtype* argument specifies one of the **S_IF*** constants defined in <*sys/stat.h*> and documented in *stat*(2) (e.g., **S_IFREG**).

RETURN VALUE

The **isfdtype**() function returns 1 if the file descriptor *fd* is of type *fdtype* and 0 if it is not. On failure, −1 is returned and *errno* is set to indicate the error.

ERRORS

The **isfdtype**() function can fail with any of the same errors as *fstat*(2).

VERSIONS

Portable applications should use *fstat*(2) instead.

STANDARDS

None.

HISTORY

It appeared in the draft POSIX.1g standard. It is present on OpenBSD and Tru64 UNIX (where the required header file in both cases is just <*sys/stat.h*>, as shown in the POSIX.1g draft).

SEE ALSO

fstat(2)

NAME

isgreater, isgreaterequal, isless, islessequal, islessgreater, isunordered − floating-point relational tests without exception for NaN

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

int isgreater(x, y);
int isgreaterequal(x, y);
int isless(x, y);
int islessequal(x, y);
int islessgreater(x, y);
int isunordered(x, y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions described here:
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The normal relational operations (like <, "less than") fail if one of the operands is NaN. This will cause an exception. To avoid this, C99 defines the macros listed below.

These macros are guaranteed to evaluate their arguments only once. The arguments must be of real floating-point type (note: do not pass integer values as arguments to these macros, since the arguments will *not* be promoted to real-floating types).

isgreater()
: determines *(x) > (y)* without an exception if *x* or *y* is NaN.

isgreaterequal()
: determines *(x) >= (y)* without an exception if *x* or *y* is NaN.

isless() determines *(x) < (y)* without an exception if *x* or *y* is NaN.

islessequal()
: determines *(x) <= (y)* without an exception if *x* or *y* is NaN.

islessgreater()
: determines *(x) < (y) || (x) > (y)* without an exception if *x* or *y* is NaN. This macro is not equivalent to *x != y* because that expression is true if *x* or *y* is NaN.

isunordered()
: determines whether its arguments are unordered, that is, whether at least one of the arguments is a NaN.

RETURN VALUE

The macros other than **isunordered**() return the result of the relational comparison; these macros return 0 if either argument is a NaN.

isunordered() returns 1 if *x* or *y* is NaN and 0 otherwise.

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
isgreater(), **isgreaterequal**(), **isless**(), **islessequal**(), **islessgreater**(), **isunordered**()	Thread safety	MT-Safe

VERSIONS

Not all hardware supports these functions, and where hardware support isn't provided, they will be emulated by macros. This will result in a performance penalty. Don't use these functions if NaN is of no concern for you.

NAME

iswalnum − test for alphanumeric wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswalnum(wint_t *wc***);**

DESCRIPTION

The **iswalnum**() function is the wide-character equivalent of the *isalnum*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "alnum".

The wide-character class "alnum" is a subclass of the wide-character class "graph", and therefore also a subclass of the wide-character class "print".

Being a subclass of the wide-character class "print", the wide-character class "alnum" is disjoint from the wide-character class "cntrl".

Being a subclass of the wide-character class "graph", the wide-character class "alnum" is disjoint from the wide-character class "space" and its subclass "blank".

The wide-character class "alnum" is disjoint from the wide-character class "punct".

The wide-character class "alnum" is the union of the wide-character classes "alpha" and "digit". As such, it also contains the wide-character class "xdigit".

The wide-character class "alnum" always contains at least the letters 'A' to 'Z', 'a' to 'z', and the digits '0' to '9'.

RETURN VALUE

The **iswalnum**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "alnum". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswalnum()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswalnum**() depends on the **LC_CTYPE** category of the current locale.

NAME

iswalpha − test for alphabetic wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswalpha(wint_t *wc***);**

DESCRIPTION

The **iswalpha**() function is the wide-character equivalent of the *isalpha*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "alpha".

The wide-character class "alpha" is a subclass of the wide-character class "alnum", and therefore also a subclass of the wide-character class "graph" and of the wide-character class "print".

Being a subclass of the wide-character class "print", the wide-character class "alpha" is disjoint from the wide-character class "cntrl".

Being a subclass of the wide-character class "graph", the wide-character class "alpha" is disjoint from the wide-character class "space" and its subclass "blank".

Being a subclass of the wide-character class "alnum", the wide-character class "alpha" is disjoint from the wide-character class "punct".

The wide-character class "alpha" is disjoint from the wide-character class "digit".

The wide-character class "alpha" contains the wide-character classes "upper" and "lower".

The wide-character class "alpha" always contains at least the letters 'A' to 'Z' and 'a' to 'z'.

RETURN VALUE

The **iswalpha**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "alpha". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

iswblank − test for whitespace wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswblank(wint_t *wc***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

iswblank():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **iswblank**() function is the wide-character equivalent of the *isblank*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "blank".

The wide-character class "blank" is a subclass of the wide-character class "space".

Being a subclass of the wide-character class "space", the wide-character class "blank" is disjoint from the wide-character class "graph" and therefore also disjoint from its subclasses "alnum", "alpha", "upper", "lower", "digit", "xdigit", "punct".

The wide-character class "blank" always contains at least the space character and the control character '\t'.

RETURN VALUE

The **iswblank**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "blank". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswblank()	Thread safety	MT-Safe locale

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

The behavior of **iswblank**() depends on the **LC_CTYPE** category of the current locale.

SEE ALSO

isblank(3), *iswctype*(3)

NAME

iswcntrl − test for control wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswcntrl(wint_t *wc***);**

DESCRIPTION

The **iswcntrl**() function is the wide-character equivalent of the *iscntrl*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "cntrl".

The wide-character class "cntrl" is disjoint from the wide-character class "print" and therefore also disjoint from its subclasses "graph", "alpha", "upper", "lower", "digit", "xdigit", "punct".

For an unsigned char *c*, *iscntrl(c)* implies *iswcntrl(btowc(c))*, but not vice versa.

RETURN VALUE

The **iswcntrl**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "cntrl". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswcntrl()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswcntrl**() depends on the **LC_CTYPE** category of the current locale.

SEE ALSO

iscntrl(3), *iswctype*(3)

NAME

iswctype − wide-character classification

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswctype(wint_t *wc***, wctype_t** *desc***);**

DESCRIPTION

If *wc* is a wide character having the character property designated by *desc* (or in other words: belongs to the character class designated by *desc*), then the **iswctype**() function returns nonzero. Otherwise, it returns zero. If *wc* is **WEOF**, zero is returned.

desc must be a character property descriptor returned by the *wctype*(3) function.

RETURN VALUE

The **iswctype**() function returns nonzero if the *wc* has the designated property. Otherwise, it returns 0.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswctype()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswctype**() depends on the **LC_CTYPE** category of the current locale.

iswalnum(3), *iswalpha*(3), *iswblank*(3), *iswcntrl*(3), *iswdigit*(3), *iswgraph*(3), *iswlower*(3), *iswprint*(3), *iswpunct*(3), *iswspace*(3), *iswupper*(3), *iswxdigit*(3), *wctype*(3)

NAME

iswdigit − test for decimal digit wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswdigit(wint_t *wc***);**

DESCRIPTION

The **iswdigit**() function is the wide-character equivalent of the *isdigit*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "digit".

The wide-character class "digit" is a subclass of the wide-character class "xdigit", and therefore also a subclass of the wide-character class "alnum", of the wide-character class "graph" and of the wide-character class "print".

Being a subclass of the wide character class "print", the wide-character class "digit" is disjoint from the wide-character class "cntrl".

Being a subclass of the wide-character class "graph", the wide-character class "digit" is disjoint from the wide-character class "space" and its subclass "blank".

Being a subclass of the wide-character class "alnum", the wide-character class "digit" is disjoint from the wide-character class "punct".

The wide-character class "digit" is disjoint from the wide-character class "alpha" and therefore also disjoint from its subclasses "lower", "upper".

The wide-character class "digit" always contains exactly the digits '0' to '9'.

RETURN VALUE

The **iswdigit**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "digit". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswdigit()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswdigit**() depends on the **LC_CTYPE** category of the current locale.

SEE ALSO

isdigit(3), *iswctype*(3)

NAME

iswgraph − test for graphic wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswgraph(wint_t *wc***);**

DESCRIPTION

The **iswgraph**() function is the wide-character equivalent of the *isgraph*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "graph".

The wide-character class "graph" is a subclass of the wide-character class "print".

Being a subclass of the wide-character class "print", the wide-character class "graph" is disjoint from the wide-character class "cntrl".

The wide-character class "graph" is disjoint from the wide-character class "space" and therefore also disjoint from its subclass "blank".

The wide-character class "graph" contains all the wide characters from the wide-character class "print" except the space character. It therefore contains the wide-character classes "alnum" and "punct".

RETURN VALUE

The **iswgraph**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "graph". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswgraph()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswgraph**() depends on the **LC_CTYPE** category of the current locale.

isgraph(3), *iswctype*(3)

NAME

iswlower − test for lowercase wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswlower(wint_t *wc***);**

DESCRIPTION

The **iswlower**() function is the wide-character equivalent of the *islower*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "lower".

The wide-character class "lower" is a subclass of the wide-character class "alpha", and therefore also a subclass of the wide-character class "alnum", of the wide-character class "graph" and of the wide-character class "print".

Being a subclass of the wide-character class "print", the wide-character class "lower" is disjoint from the wide-character class "cntrl".

Being a subclass of the wide-character class "graph", the wide-character class "lower" is disjoint from the wide-character class "space" and its subclass "blank".

Being a subclass of the wide-character class "alnum", the wide-character class "lower" is disjoint from the wide-character class "punct".

Being a subclass of the wide-character class "alpha", the wide-character class "lower" is disjoint from the wide-character class "digit".

The wide-character class "lower" contains at least those characters *wc* which are equal to *towlower(wc)* and different from *towupper(wc)*.

The wide-character class "lower" always contains at least the letters 'a' to 'z'.

RETURN VALUE

The **iswlower**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "lower". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswlower()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswlower**() depends on the **LC_CTYPE** category of the current locale.

This function is not very appropriate for dealing with Unicode characters, because Unicode knows about three cases: upper, lower, and title case.

SEE ALSO

islower(3), *iswctype*(3), *towlower*(3)

NAME

iswprint − test for printing wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswprint(wint_t *wc***);**

DESCRIPTION

The **iswprint**() function is the wide-character equivalent of the *isprint*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "print".

The wide-character class "print" is disjoint from the wide-character class "cntrl".

The wide-character class "print" contains the wide-character class "graph".

RETURN VALUE

The **iswprint**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "print". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswprint()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswprint**() depends on the **LC_CTYPE** category of the current locale.

SEE ALSO

isprint(3), *iswctype*(3)

NAME

iswpunct − test for punctuation or symbolic wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswpunct(wint_t *wc***);**

DESCRIPTION

The **iswpunct**() function is the wide-character equivalent of the *ispunct*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "punct".

The wide-character class "punct" is a subclass of the wide-character class "graph", and therefore also a subclass of the wide-character class "print".

The wide-character class "punct" is disjoint from the wide-character class "alnum" and therefore also disjoint from its subclasses "alpha", "upper", "lower", "digit", "xdigit".

Being a subclass of the wide-character class "print", the wide-character class "punct" is disjoint from the wide-character class "cntrl".

Being a subclass of the wide-character class "graph", the wide-character class "punct" is disjoint from the wide-character class "space" and its subclass "blank".

RETURN VALUE

The **iswpunct**() function returns nonzero if *wc* is a wide-character belonging to the wide-character class "punct". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswpunct()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **iswpunct**() depends on the **LC_CTYPE** category of the current locale.

This function’s name is a misnomer when dealing with Unicode characters, because the wide-character class "punct" contains both punctuation characters and symbol (math, currency, etc.) characters.

SEE ALSO

ispunct(3), *iswctype*(3)

NAME

iswspace − test for whitespace wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswspace(wint_t *wc***);**

DESCRIPTION

The **iswspace**() function is the wide-character equivalent of the *isspace*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "space".

The wide-character class "space" is disjoint from the wide-character class "graph" and therefore also disjoint from its subclasses "alnum", "alpha", "upper", "lower", "digit", "xdigit", "punct".

The wide-character class "space" contains the wide-character class "blank".

The wide-character class "space" always contains at least the space character and the control characters '\f', '\n', '\r', '\t', and '\v'.

RETURN VALUE

The **iswspace**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "space". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswspace()	Thread safety	MT-Safe locale

STANDARDS

NAME

iswupper − test for uppercase wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

int iswupper(wint_t *wc***);**

DESCRIPTION

The **iswupper**() function is the wide-character equivalent of the *isupper*(3) function. It tests whether *wc* is a wide character belonging to the wide-character class "upper".

The wide-character class "upper" is a subclass of the wide-character class "alpha", and therefore also a subclass of the wide-character class "alnum", of the wide-character class "graph" and of the wide-character class "print".

Being a subclass of the wide-character class "print", the wide-character class "upper" is disjoint from the wide-character class "cntrl".

Being a subclass of the wide-character class "graph", the wide-character class "upper" is disjoint from the wide-character class "space" and its subclass "blank".

Being a subclass of the wide-character class "alnum", the wide-character class "upper" is disjoint from the wide-character class "punct".

Being a subclass of the wide-character class "alpha", the wide-character class "upper" is disjoint from the wide-character class "digit".

The wide-character class "upper" contains at least those characters *wc* which are equal to *towupper(wc)* and different from *towlower(wc)*.

The wide-character class "upper" always contains at least the letters 'A' to 'Z'.

RETURN VALUE

The **iswupper**() function returns nonzero if *wc* is a wide character belonging to the wide-character class "upper". Otherwise, it returns zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
iswupper()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

NAME

j0, j0f, j0l, j1, j1f, j1l, jn, jnf, jnl − Bessel functions of the first kind

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double j0(double x);
double j1(double x);
double jn(int n, double x);

float j0f(float x);
float j1f(float x);
float jnf(int n, float x);

long double j0l(long double x);
long double j1l(long double x);
long double jnl(int n, long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

j0(), **j1**(), **jn**():
_XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

j0f(), **j0l**(), **j1f**(), **j1l**(), **jnf**(), **jnl**():
_XOPEN_SOURCE >= 600
|| (_ISOC99_SOURCE && _XOPEN_SOURCE)
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

DESCRIPTION

The **j0**() and **j1**() functions return Bessel functions of *x* of the first kind of orders 0 and 1, respectively. The **jn**() function returns the Bessel function of *x* of the first kind of order *n*.

The **j0f**(), **j1f**(), and **jnf**(), functions are versions that take and return *float* values. The **j0l**(), **j1l**(), and **jnl**() functions are versions that take and return *long double* values.

RETURN VALUE

On success, these functions return the appropriate Bessel value of the first kind for *x*.

If *x* is a NaN, a NaN is returned.

If *x* is too large in magnitude, or the result underflows, a range error occurs, and the return value is 0.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result underflow, or *x* is too large in magnitude
errno is set to **ERANGE**.

These functions do not raise exceptions for *fetestexcept*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

Others: BSD.

BUGS

There are errors of up to 2e−16 in the values returned by **j0**(), **j1**(), and **jn**() for values of *x* between −8 and 8.

SEE ALSO

y0(3)

NAME

key_decryptsession, key_encryptsession, key_setsecret, key_gendes, key_secretkey_is_set − interfaces to rpc keyserver daemon

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <rpc/rpc.h>

int key_decryptsession(char ****remotename*, des_block ****deskey***);**
int key_encryptsession(char ****remotename*, des_block ****deskey***);**

int key_gendes(des_block ****deskey*);**

int key_setsecret(char ****key*);**
int key_secretkey_is_set(void);

DESCRIPTION

The functions here are used within the RPC's secure authentication mechanism (AUTH_DES). There should be no need for user programs to use this functions.

The function **key_decryptsession**() uses the (remote) server netname and takes the DES key for decrypting. It uses the public key of the server and the secret key associated with the effective UID of the calling process.

The function **key_encryptsession**() is the inverse of **key_decryptsession**(). It encrypts the DES keys with the public key of the server and the secret key associated with the effective UID of the calling process.

The function **key_gendes**() is used to ask the keyserver for a secure conversation key.

The function **key_setsecret**() is used to set the key for the effective UID of the calling process.

The function **key_secretkey_is_set**() can be used to determine whether a key has been set for the effective UID of the calling process.

RETURN VALUE

These functions return 1 on success and 0 on failure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
key_decryptsession(), **key_encryptsession**(), **key_gendes**(), **key_setsecret**(), **key_secretkey_is_set**()	Thread safety	MT-Safe

NOTES

Note that we talk about two types of encryption here. One is asymmetric using a public and secret key. The other is symmetric, the 64-bit DES.

These routines were part of the Linux/Doors-project, abandoned by now.

SEE ALSO

crypt(3)

NAME

killpg − send signal to a process group

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>

int killpg(int pgrp, int sig);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

killpg():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE

DESCRIPTION

killpg() sends the signal *sig* to the process group *pgrp*. See *signal*(7) for a list of signals.

If *pgrp* is 0, **killpg**() sends the signal to the calling process's process group. (POSIX says: if *pgrp* is less than or equal to 1, the behavior is undefined.)

For the permissions required to send a signal to another process, see *kill*(2).

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL
sig is not a valid signal number.

EPERM
The process does not have permission to send the signal to any of the target processes. For the required permissions, see *kill*(2).

ESRCH
No process can be found in the process group specified by *pgrp*.

ESRCH
The process group was given as 0 but the sending process does not have a process group.

VERSIONS

There are various differences between the permission checking in BSD-type systems and System V-type systems. See the POSIX rationale for *kill*(3p)A difference not mentioned by POSIX concerns the return value **EPERM**: BSD documents that no signal is sent and **EPERM** returned when the permission check failed for at least one target process, while POSIX documents **EPERM** only when the permission check failed for all target processes.

C library/kernel differences

On Linux, **killpg**() is implemented as a library function that makes the call *kill(−pgrp, sig)*.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.4BSD (first appeared in 4BSD).

SEE ALSO

getpgrp(2), *kill*(2), *signal*(2), *capabilities*(7), *credentials*(7)

NAME

ldexp, ldexpf, ldexpl − multiply floating-point number by integral power of 2

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double ldexp(double x, int exp);
float ldexpf(float x, int exp);
long double ldexpl(long double x, int exp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ldexpf(), **ldexpl**():

```
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
    || /* Since glibc 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

DESCRIPTION

These functions return the result of multiplying the floating-point number *x* by 2 raised to the power *exp*.

RETURN VALUE

On success, these functions return *x * (2^exp)*.

If *exp* is zero, then *x* is returned.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity (negative infinity), positive infinity (negative infinity) is returned.

If the result underflows, a range error occurs, and zero is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with a sign the same as *x*.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error, overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error, underflow
: *errno* is set to **ERANGE**. An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ldexp(), **ldexpf**(), **ldexpl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

NAME

lgamma, lgammaf, lgammal, lgamma_r, lgammaf_r, lgammal_r, signgam − log gamma function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double lgamma(double x);
float lgammaf(float x);
long double lgammal(long double x);

double lgamma_r(double x, int *signp);
float lgammaf_r(float x, int *signp);
long double lgammal_r(long double x, int *signp);

extern int signgam;
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

lgamma():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L || _XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

lgammaf(), **lgammal**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

lgamma_r(), **lgammaf_r**(), **lgammal_r**():
/* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

signgam:
_XOPEN_SOURCE
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

For the definition of the Gamma function, see *tgamma*(3).

The **lgamma**(), **lgammaf**(), and **lgammal**() functions return the natural logarithm of the absolute value of the Gamma function. The sign of the Gamma function is returned in the external integer *signgam* declared in <*math.h*>. It is 1 when the Gamma function is positive or zero, −1 when it is negative.

Since using a constant location *signgam* is not thread-safe, the functions **lgamma_r**(), **lgammaf_r**(), and **lgammal_r**() have been introduced; they return the sign via the argument *signp*.

RETURN VALUE

On success, these functions return the natural logarithm of Gamma(x).

If *x* is a NaN, a NaN is returned.

If *x* is 1 or 2, +0 is returned.

If *x* is positive infinity or negative infinity, positive infinity is returned.

If *x* is a nonpositive integer, a pole error occurs, and the functions return +**HUGE_VAL**, +**HUGE_VALF**, or +**HUGE_VALL**, respectively.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the correct mathematical sign.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Pole error: *x* is a nonpositive integer
: *errno* is set to **ERANGE** (but see BUGS). A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

Range error: result overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

STANDARDS

lgamma()
lgammaf()
lgammal()
: C11, POSIX.1-2008.

signgam
: POSIX.1-2008.

lgamma_r()
lgammaf_r()
lgammal_r()
: None.

HISTORY

lgamma()
lgammaf()
lgammal()
: C99, POSIX.1-2001.

signgam
: POSIX.1-2001.

lgamma_r()
lgammaf_r()
lgammal_r()
: None.

BUGS

In glibc 2.9 and earlier, when a pole error occurs, *errno* is set to **EDOM**; instead of the POSIX-mandated **ERANGE**. Since glibc 2.10, glibc does the right thing.

SYNOPSIS

```
#include <aio.h>

int lio_listio(int mode,
               struct aiocb *restrict const aiocb_list[restrict],
               int nitems, struct sigevent *restrict sevp);
```

DESCRIPTION

The **lio_listio**() function initiates the list of I/O operations described by the array *aiocb_list*.

The *mode* operation has one of the following values:

LIO_WAIT
: The call blocks until all operations are complete. The *sevp* argument is ignored.

LIO_NOWAIT
: The I/O operations are queued for processing and the call returns immediately. When all of the I/O operations complete, asynchronous notification occurs, as specified by the *sevp* argument; see *sigevent*(3type) for details. If *sevp* is NULL, no asynchronous notification occurs.

The *aiocb_list* argument is an array of pointers to *aiocb* structures that describe I/O operations. These operations are executed in an unspecified order. The *nitems* argument specifies the size of the array *aiocb_list*. Null pointers in *aiocb_list* are ignored.

In each control block in *aiocb_list*, the *aio_lio_opcode* field specifies the I/O operation to be initiated, as follows:

LIO_READ
: Initiate a read operation. The operation is queued as for a call to *aio_read*(3) specifying this control block.

LIO_WRITE
: Initiate a write operation. The operation is queued as for a call to *aio_write*(3) specifying this control block.

LIO_NOP
: Ignore this control block.

The remaining fields in each control block have the same meanings as for *aio_read*(3) and *aio_write*(3). The *aio_sigevent* fields of each control block can be used to specify notifications for the individual I/O operations (see *sigevent*(7)).

RETURN VALUE

If *mode* is **LIO_NOWAIT**, **lio_listio**() returns 0 if all I/O operations are successfully queued. Otherwise, −1 is returned, and *errno* is set to indicate the error.

If *mode* is **LIO_WAIT**, **lio_listio**() returns 0 when all of the I/O operations have completed successfully. Otherwise, −1 is returned, and *errno* is set to indicate the error.

The return status from **lio_listio**() provides information only about the call itself, not about the individual I/O operations. One or more of the I/O operations may fail, but this does not prevent other operations completing. The status of individual I/O operations in *aiocb_list* can be determined using *aio_error*(3). When an operation has completed, its return status can be obtained using *aio_return*(3). Individual I/O operations can fail for the reasons described in *aio_read*(3) and *aio_write*(3).

ERRORS

The **lio_listio**() function may fail for the following reasons:

EAGAIN
: Out of resources.

EAGAIN
: The number of I/O operations specified by *nitems* would cause the limit **AIO_MAX** to be exceeded.

EINTR
mode was **LIO_WAIT** and a signal was caught before all I/O operations completed; see *signal*(7). (This may even be one of the signals used for asynchronous I/O completion notification.)

EINVAL
mode is invalid, or *nitems* exceeds the limit **AIO_LISTIO_MAX**.

EIO One of more of the operations specified by *aiocb_list* failed. The application can check the status of each operation using *aio_return*(3).

If **lio_listio**() fails with the error **EAGAIN**, **EINTR**, or **EIO**, then some of the operations in *aiocb_list* may have been initiated. If **lio_listio**() fails for any other reason, then none of the I/O operations has been initiated.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
lio_listio()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

NOTES

It is a good idea to zero out the control blocks before use. The control blocks must not be changed while the I/O operations are in progress. The buffer areas being read into or written from must not be accessed during the operations or undefined results may occur. The memory areas involved must remain valid.

Simultaneous I/O operations specifying the same *aiocb* structure produce undefined results.

NAME

LIST_EMPTY, LIST_ENTRY, LIST_FIRST, LIST_FOREACH, LIST_HEAD, LIST_HEAD_INITIALIZER, LIST_INIT, LIST_INSERT_AFTER, LIST_INSERT_BEFORE, LIST_INSERT_HEAD, LIST_NEXT, LIST_REMOVE − implementation of a doubly linked list

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/queue.h>

LIST_ENTRY(TYPE);

LIST_HEAD(HEADNAME, TYPE);
LIST_HEAD LIST_HEAD_INITIALIZER(LIST_HEAD *head***);**
void LIST_INIT(LIST_HEAD * *head***);**

int LIST_EMPTY(LIST_HEAD * *head***);**

void LIST_INSERT_HEAD(LIST_HEAD * *head***,**
struct TYPE * *elm***, LIST_ENTRY** *NAME***);**
void LIST_INSERT_BEFORE(struct TYPE * *listelm***,**
struct TYPE * *elm***, LIST_ENTRY** *NAME***);**
void LIST_INSERT_AFTER(struct TYPE * *listelm***,**
struct TYPE * *elm***, LIST_ENTRY** *NAME***);**

struct TYPE *LIST_FIRST(LIST_HEAD * *head***);**
struct TYPE *LIST_NEXT(struct TYPE * *elm***, LIST_ENTRY** *NAME***);**

LIST_FOREACH(struct TYPE * *var***, LIST_HEAD *** *head***, LIST_ENTRY** *NAME***);**

void LIST_REMOVE(struct TYPE * *elm***, LIST_ENTRY** *NAME***);**

DESCRIPTION

These macros define and operate on doubly linked lists.

In the macro definitions, *TYPE* is the name of a user-defined structure, that must contain a field of type *LIST_ENTRY*, named *NAME*. The argument *HEADNAME* is the name of a user-defined structure that must be declared using the macro **LIST_HEAD**().

Creation

A list is headed by a structure defined by the **LIST_HEAD**() macro. This structure contains a single pointer to the first element on the list. The elements are doubly linked so that an arbitrary element can be removed without traversing the list. New elements can be added to the list after an existing element, before an existing element, or at the head of the list. A *LIST_HEAD* structure is declared as follows:

```
LIST_HEAD(HEADNAME, TYPE) head;
```

where *struct HEADNAME* is the structure to be defined, and *struct TYPE* is the type of the elements to be linked into the list. A pointer to the head of the list can later be declared as:

```
struct HEADNAME *headp;
```

(The names *head* and *headp* are user selectable.)

LIST_ENTRY() declares a structure that connects the elements in the list.

LIST_HEAD_INITIALIZER() evaluates to an initializer for the list *head*.

LIST_INIT() initializes the list referenced by *head*.

LIST_EMPTY() evaluates to true if there are no elements in the list.

Insertion

LIST_INSERT_HEAD() inserts the new element *elm* at the head of the list.

LIST_INSERT_BEFORE() inserts the new element *elm* before the element *listelm*.

LIST_INSERT_AFTER() inserts the new element *elm* after the element *listelm*.

Traversal

LIST_FIRST() returns the first element in the list, or NULL if the list is empty.

LIST_NEXT() returns the next element in the list, or NULL if this is the last.

LIST_FOREACH() traverses the list referenced by *head* in the forward direction, assigning each element in turn to *var*.

Removal

LIST_REMOVE() removes the element *elm* from the list.

RETURN VALUE

LIST_EMPTY() returns nonzero if the list is empty, and zero if the list contains at least one entry.

LIST_FIRST(), and **LIST_NEXT**() return a pointer to the first or next *TYPE* structure, respectively.

LIST_HEAD_INITIALIZER() returns an initializer that can be assigned to the list *head*.

STANDARDS

BSD.

HISTORY

4.4BSD.

BUGS

LIST_FOREACH() doesn't allow *var* to be removed or freed within the loop, as it would interfere with the traversal. **LIST_FOREACH_SAFE**(), which is present on the BSDs but is not present in glibc, fixes this limitation by allowing *var* to safely be removed from the list and freed from within the loop without interfering with the traversal.

EXAMPLES

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/queue.h>

struct entry {
    int data;
    LIST_ENTRY(entry) entries;              /* List */
};

LIST_HEAD(listhead, entry);

int
main(void)
{
    struct entry *n1, *n2, *n3, *np;
    struct listhead head;                   /* List head */
    int i;

    LIST_INIT(&head);                       /* Initialize the list */

    n1 = malloc(sizeof(struct entry));      /* Insert at the head */
    LIST_INSERT_HEAD(&head, n1, entries);

    n2 = malloc(sizeof(struct entry));      /* Insert after */
    LIST_INSERT_AFTER(n1, n2, entries);

    n3 = malloc(sizeof(struct entry));      /* Insert before */
    LIST_INSERT_BEFORE(n2, n3, entries);

    i = 0;                                  /* Forward traversal */
    LIST_FOREACH(np, &head, entries)
        np->data = i++;

    LIST_REMOVE(n2, entries);               /* Deletion */
    free(n2);
                                            /* Forward traversal */
```

```
        LIST_FOREACH(np, &head, entries)
            printf("%i\n", np->data);
                                                /* List deletion */
        n1 = LIST_FIRST(&head);
        while (n1 != NULL) {
            n2 = LIST_NEXT(n1, entries);
            free(n1);
            n1 = n2;
        }
        LIST_INIT(&head);

        exit(EXIT_SUCCESS);
    }
```

NAME

localeconv − get numeric formatting information

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <locale.h>

struct lconv *localeconv(void);

DESCRIPTION

The **localeconv**() function returns a pointer to a *struct lconv* for the current locale. This structure is shown in *locale*(7), and contains all values associated with the locale categories **LC_NUMERIC** and **LC_MONETARY**. Programs may also use the functions *printf*(3) and *strfmon*(3), which behave according to the actual locale in use.

RETURN VALUE

The **localeconv**() function returns a pointer to a filled in *struct lconv*. This structure may be (in glibc, *is*) statically allocated, and may be overwritten by subsequent calls. According to POSIX, the caller should not modify the contents of this structure. The **localeconv**() function always succeeds.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

lockf − apply, test or remove a POSIX lock on an open file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

int lockf(int *fd***, int** *op***, off_t** *len***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

lockf():
_XOPEN_SOURCE >= 500
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

Apply, test, or remove a POSIX lock on a section of an open file. The file is specified by *fd*, a file descriptor open for writing, the action by *op*, and the section consists of byte positions *pos*..*pos*+*len*−1 if *len* is positive, and *pos*−*len*..*pos*−1 if *len* is negative, where *pos* is the current file position, and if *len* is zero, the section extends from the current file position to infinity, encompassing the present and future end-of-file positions. In all cases, the section may extend past current end-of-file.

On Linux, **lockf**() is just an interface on top of *fcntl*(2) locking. Many other systems implement **lockf**() in this way, but note that POSIX.1 leaves the relationship between **lockf**() and *fcntl*(2) locks unspecified. A portable application should probably avoid mixing calls to these interfaces.

Valid operations are given below:

F_LOCK
: Set an exclusive lock on the specified section of the file. If (part of) this section is already locked, the call blocks until the previous lock is released. If this section overlaps an earlier locked section, both are merged. File locks are released as soon as the process holding the locks closes some file descriptor for the file. A child process does not inherit these locks.

F_TLOCK
: Same as **F_LOCK** but the call never blocks and returns an error instead if the file is already locked.

F_ULOCK
: Unlock the indicated section of the file. This may cause a locked section to be split into two locked sections.

F_TEST
: Test the lock: return 0 if the specified section is unlocked or locked by this process; return −1, set *errno* to **EAGAIN** (**EACCES** on some other systems), if another process holds a lock.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EACCES or **EAGAIN**
: The file is locked and **F_TLOCK** or **F_TEST** was specified, or the operation is prohibited because the file has been memory-mapped by another process.

EBADF
: *fd* is not an open file descriptor; or *op* is **F_LOCK** or **F_TLOCK** and *fd* is not a writable file descriptor.

EDEADLK
: *op* was **F_LOCK** and this lock operation would cause a deadlock.

EINTR
: While waiting to acquire a lock, the call was interrupted by delivery of a signal caught by a handler; see *signal*(7).

EINVAL
An invalid operation was specified in *op*.

ENOLCK
Too many segment locks open, lock table is full.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
lockf()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

NAME

log, logf, logl − natural logarithmic function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double log(double x);
float logf(float x);
long double logl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

logf(), **logl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the natural logarithm of *x*.

RETURN VALUE

On success, these functions return the natural logarithm of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is 1, the result is +0.

If *x* is positive infinity, positive infinity is returned.

If *x* is zero, then a pole error occurs, and the functions return **−HUGE_VAL**, **−HUGE_VALF**, or **−HUGE_VALL**, respectively.

If *x* is negative (including negative infinity), then a domain error occurs, and a NaN (not a number) is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is negative
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

Pole error: *x* is zero
: *errno* is set to **ERANGE**. A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
log(), **logf**(), **logl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

BUGS

In glibc 2.5 and earlier, taking the **log**() of a NaN produces a bogus invalid floating-point (**FE_INVALID**) exception.

|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return a value equivalent to

log (1 + *x*)

The result is computed in a way that is accurate even if the value of *x* is near zero.

RETURN VALUE

On success, these functions return the natural logarithm of *(1 + x)*.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity, positive infinity is returned.

If *x* is −1, a pole error occurs, and the functions return −**HUGE_VAL**, −**HUGE_VALF**, or −**HUGE_VALL**, respectively.

If *x* is less than −1 (including negative infinity), a domain error occurs, and a NaN (not a number) is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is less than −1
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

Pole error: *x* is −1
: *errno* is set to **ERANGE** (but see BUGS). A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

logb, logbf, logbl − get exponent of a floating-point value

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double logb(double x);
float logbf(float x);
long double logbl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

logb():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

logbf(), **logbl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions extract the exponent from the internal floating-point representation of *x* and return it as a floating-point value. The integer constant **FLT_RADIX**, defined in <*float.h*>, indicates the radix used for the system's floating-point representation. If **FLT_RADIX** is 2, **logb(***x***)** is similar to **floor(log2(fabs(***x***)))**, except that the latter may give an incorrect integer due to intermediate rounding.

If *x* is subnormal, **logb**() returns the exponent *x* would have if it were normalized.

RETURN VALUE

On success, these functions return the exponent of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is zero, then a pole error occurs, and the functions return **−HUGE_VAL**, **−HUGE_VALF**, or **−HUGE_VALL**, respectively.

If *x* is negative infinity or positive infinity, then positive infinity is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Pole error: *x* is 0
A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

These functions do not set *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

login, logout − write utmp and wtmp entries

LIBRARY

System utilities library (*libutil*, *−lutil*)

SYNOPSIS

#include <utmp.h>

void login(const struct utmp ****ut*);**
int logout(const char ****ut_line*);**

DESCRIPTION

The utmp file records who is currently using the system. The wtmp file records all logins and logouts. See *utmp*(5).

The function **login**() takes the supplied *struct utmp*, *ut*, and writes it to both the utmp and the wtmp file.

The function **logout**() clears the entry in the utmp file again.

GNU details

More precisely, **login**() takes the argument *ut* struct, fills the field *ut−>ut_type* (if there is such a field) with the value **USER_PROCESS**, and fills the field *ut−>ut_pid* (if there is such a field) with the process ID of the calling process. Then it tries to fill the field *ut−>ut_line*. It takes the first of *stdin*, *stdout*, *stderr* that is a terminal, and stores the corresponding pathname minus a possible leading */dev/* into this field, and then writes the struct to the utmp file. On the other hand, if no terminal name was found, this field is filled with "???" and the struct is not written to the utmp file. After this, the struct is written to the wtmp file.

The **logout**() function searches the utmp file for an entry matching the *ut_line* argument. If a record is found, it is updated by zeroing out the *ut_name* and *ut_host* fields, updating the *ut_tv* timestamp field and setting *ut_type* (if there is such a field) to **DEAD_PROCESS**.

RETURN VALUE

The **logout**() function returns 1 if the entry was successfully written to the database, or 0 if an error occurred.

FILES

/var/run/utmp
: user accounting database, configured through **_PATH_UTMP** in <*paths.h*>

/var/log/wtmp
: user accounting log file, configured through **_PATH_WTMP** in <*paths.h*>

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
login(), **logout**()	Thread safety	MT-Unsafe race:utent sig:ALRM timer

In the above table, *utent* in *race:utent* signifies that if any of the functions *setutent*(3), *getutent*(3), or *endutent*(3) are used in parallel in different threads of a program, then data races could occur. **login**() and **logout**() calls those functions, so we use race:utent to remind users.

VERSIONS

The member *ut_user* of *struct utmp* is called *ut_name* in BSD. Therefore, *ut_name* is defined as an alias for *ut_user* in <*utmp.h*>.

STANDARDS

BSD.

lrint, lrintf, lrintl, llrint, llrintf, llrintl − round to nearest integer

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

long lrint(double x);
long lrintf(float x);
long lrintl(long double x);

long long llrint(double x);
long long llrintf(float x);
long long llrintl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions round their argument to the nearest integer value, using the current rounding direction (see *fesetround*(3)).

Note that unlike the *rint*(3) family of functions, the return type of these functions differs from that of their arguments.

RETURN VALUE

These functions return the rounded integer value.

If *x* is a NaN or an infinity, or the rounded value is too large to be stored in a *long* (*long long* in the case of the **ll*** functions), then a domain error occurs, and the return value is unspecified.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is a NaN or infinite, or the rounded value is too large
An invalid floating-point exception (**FE_INVALID**) is raised.

These functions do not set *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
lrint(), **lrintf**(), **lrintl**(), **llrint**(), **llrintf**(), **llrintl**()	Thread safety	MT-Safe

NAME

lround, lroundf, lroundl, llround, llroundf, llroundl − round to nearest integer

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

long lround(double x);
long lroundf(float x);
long lroundl(long double x);

long long llround(double x);
long long llroundf(float x);
long long llroundl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions round their argument to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding direction (see *fenv*(3)).

Note that unlike the *round*(3) and *ceil*(3), functions, the return type of these functions differs from that of their arguments.

RETURN VALUE

These functions return the rounded integer value.

If *x* is a NaN or an infinity, or the rounded value is too large to be stored in a *long* (*long long* in the case of the **ll*** functions), then a domain error occurs, and the return value is unspecified.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is a NaN or infinite, or the rounded value is too large
An invalid floating-point exception (**FE_INVALID**) is raised.

These functions do not set *errno*.

ATTRIBUTES

NAME

lfind, lsearch − linear search of an array

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <search.h>

void *lfind(const void key[.size], const void base[.size * .nmemb],
        size_t *nmemb, size_t size,
        int(*compar)(const void [.size], const void [.size]));
void *lsearch(const void key[.size], void base[.size * .nmemb],
        size_t *nmemb, size_t size,
        int(*compar)(const void [.size], const void [.size]));
```

DESCRIPTION

lfind() and **lsearch**() perform a linear search for *key* in the array *base* which has **nmemb* elements of *size* bytes each. The comparison function referenced by *compar* is expected to have two arguments which point to the *key* object and to an array member, in that order, and which returns zero if the *key* object matches the array member, and nonzero otherwise.

If **lsearch**() does not find a matching element, then the *key* object is inserted at the end of the table, and **nmemb* is incremented. In particular, one should know that a matching element exists, or that more room is available.

RETURN VALUE

lfind() returns a pointer to a matching member of the array, or NULL if no match is found. **lsearch**() returns a pointer to a matching member of the array, or to the newly added member if no match is found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
lfind(), **lsearch**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD. libc-4.6.27.

BUGS

The naming is unfortunate.

NAME

lseek64 − reposition 64-bit read/write file offset

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _LARGEFILE64_SOURCE     /* See feature_test_macros(7) */
#include <sys/types.h>
#include <unistd.h>

off64_t lseek64(int fd, off64_t offset, int whence);
```

DESCRIPTION

The **lseek**() family of functions reposition the offset of the open file associated with the file descriptor *fd* to *offset* bytes relative to the start, current position, or end of the file, when *whence* has the value **SEEK_SET**, **SEEK_CUR**, or **SEEK_END**, respectively.

For more details, return value, and errors, see *lseek*(2).

Four interfaces are available: **lseek**(), **lseek64**(), **llseek**(), and **_llseek**().

lseek()

Prototype:

```
off_t lseek(int fd, off_t offset, int whence);
```

The C library's **lseek**() wrapper function uses the type *off_t*. This is a 32-bit signed type on 32-bit architectures, unless one compiles with

```
#define _FILE_OFFSET_BITS 64
```

in which case it is a 64-bit signed type.

lseek64()

Prototype:

```
off64_t lseek64(int fd, off64_t offset, int whence);
```

The **lseek64**() library function uses a 64-bit type even when *off_t* is a 32-bit type. Its prototype (and the type *off64_t*) is available only when one compiles with

```
#define _LARGEFILE64_SOURCE
```

The function **lseek64**() is available since glibc 2.1.

llseek()

Prototype:

```
loff_t llseek(int fd, loff_t offset, int whence);
```

The type *loff_t* is a 64-bit signed type. The **llseek**() library function is available in glibc and works without special defines. However, the glibc headers do not provide a prototype. Users should add the above prototype, or something equivalent, to their own source. When users complained about data loss caused by a miscompilation of *e2fsck*(8), glibc 2.1.3 added the link-time warning

"the `llseek´ function may be dangerous; use `lseek64´ instead."

This makes this function unusable if one desires a warning-free compilation.

Since glibc 2.28, this function symbol is no longer available to newly linked applications.

_llseek()

On 32-bit architectures, this is the system call that is used (by the C library wrapper functions) to implement all of the above functions. The prototype is:

```
int _llseek(int fd, off_t offset_hi, off_t offset_lo,
            loff_t *result, int whence);
```

For more details, see *llseek*(2).

64-bit systems don't need an **_llseek**() system call. Instead, they have an *lseek*(2) system call that supports 64-bit file offsets.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
lseek64()	Thread safety	MT-Safe

NOTES

lseek64() is one of the functions that was specified in the Large File Summit (LFS) specification that was completed in 1996. The purpose of the specification was to provide transitional support that allowed applications on 32-bit systems to access files whose size exceeds that which can be represented with a 32-bit *off_t* type. As noted above, this symbol is exposed by header files if the **_LARGEFILE64_SOURCE** feature test macro is defined. ALternatively, on a 32-bit system, the symbol *lseek* is aliased to *lseek64* if the macro **_FILE_OFFSET_BITS** is defined with the value 64.

NAME

makecontext, swapcontext − manipulate user context

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <ucontext.h>

void makecontext(ucontext_t ****ucp*, void (*** *func***)(), int** *argc***, ...);**
int swapcontext(ucontext_t *restrict *oucp***,**
const ucontext_t *restrict *ucp***);**

DESCRIPTION

In a System V-like environment, one has the type *ucontext_t* (defined in <*ucontext.h*> and described in *getcontext*(3)) and the four functions *getcontext*(3), *setcontext*(3), **makecontext**(), and **swapcontext**() that allow user-level context switching between multiple threads of control within a process.

The **makecontext**() function modifies the context pointed to by *ucp* (which was obtained from a call to *getcontext*(3)). Before invoking **makecontext**(), the caller must allocate a new stack for this context and assign its address to *ucp−>uc_stack*, and define a successor context and assign its address to *ucp−>uc_link*.

When this context is later activated (using *setcontext*(3) or *swapcontext*()) the function *func* is called, and passed the series of integer (*int*) arguments that follow *argc*; the caller must specify the number of these arguments in *argc*. When this function returns, the successor context is activated. If the successor context pointer is NULL, the thread exits.

The **swapcontext**() function saves the current context in the structure pointed to by *oucp*, and then activates the context pointed to by *ucp*.

RETURN VALUE

When successful, **swapcontext**() does not return. (But we may return later, in case *oucp* is activated, in which case it looks like **swapcontext**() returns 0.) On error, **swapcontext**() returns −1 and sets *errno* to indicate the error.

ERRORS

ENOMEM
Insufficient stack space left.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
makecontext()	Thread safety	MT-Safe race:ucp
swapcontext()	Thread safety	MT-Safe race:oucp race:ucp

STANDARDS

None.

HISTORY

glibc 2.1. SUSv2, POSIX.1-2001. Removed in POSIX.1-2008, citing portability issues, and recommending that applications be rewritten to use POSIX threads instead.

NOTES

The interpretation of *ucp−>uc_stack* is just as in *sigaltstack*(2), namely, this struct contains the start and length of a memory area to be used as the stack, regardless of the direction of growth of the stack. Thus, it is not necessary for the user program to worry about this direction.

On architectures where *int* and pointer types are the same size (e.g., x86-32, where both types are 32 bits), you may be able to get away with passing pointers as arguments to **makecontext**() following *argc*. However, doing this is not guaranteed to be portable, is undefined according to the standards, and won't work on architectures where pointers are larger than *int*s. Nevertheless, starting with glibc 2.8, glibc makes some changes to **makecontext**(), to permit this on some 64-bit architectures (e.g., x86-64).

EXAMPLES

The example program below demonstrates the use of *getcontext*(3), **makecontext**(), and **swapcontext**(). Running the program produces the following output:

```
$ ./a.out
main: swapcontext(&uctx_main, &uctx_func2)
func2: started
func2: swapcontext(&uctx_func2, &uctx_func1)
func1: started
func1: swapcontext(&uctx_func1, &uctx_func2)
func2: returning
func1: returning
main: exiting
```

Program source

```
#include <stdio.h>
#include <stdlib.h>
#include <ucontext.h>

static ucontext_t uctx_main, uctx_func1, uctx_func2;

#define handle_error(msg) \
    do { perror(msg); exit(EXIT_FAILURE); } while (0)

static void
func1(void)
{
    printf("%s: started\n", __func__);
    printf("%s: swapcontext(&uctx_func1, &uctx_func2)\n", __func__);
    if (swapcontext(&uctx_func1, &uctx_func2) == -1)
        handle_error("swapcontext");
    printf("%s: returning\n", __func__);
}

static void
func2(void)
{
    printf("%s: started\n", __func__);
    printf("%s: swapcontext(&uctx_func2, &uctx_func1)\n", __func__);
    if (swapcontext(&uctx_func2, &uctx_func1) == -1)
        handle_error("swapcontext");
    printf("%s: returning\n", __func__);
}

int
main(int argc, char *argv[])
{
    char func1_stack[16384];
    char func2_stack[16384];

    if (getcontext(&uctx_func1) == -1)
        handle_error("getcontext");
    uctx_func1.uc_stack.ss_sp = func1_stack;
    uctx_func1.uc_stack.ss_size = sizeof(func1_stack);
    uctx_func1.uc_link = &uctx_main;
    makecontext(&uctx_func1, func1, 0);

    if (getcontext(&uctx_func2) == -1)
        handle_error("getcontext");
    uctx_func2.uc_stack.ss_sp = func2_stack;
    uctx_func2.uc_stack.ss_size = sizeof(func2_stack);
    /* Successor context is f1(), unless argc > 1 */
```

```
        uctx_func2.uc_link = (argc > 1) ? NULL : &uctx_func1;
        makecontext(&uctx_func2, func2, 0);

        printf("%s: swapcontext(&uctx_main, &uctx_func2)\n", __func__);
        if (swapcontext(&uctx_main, &uctx_func2) == -1)
            handle_error("swapcontext");

        printf("%s: exiting\n", __func__);
        exit(EXIT_SUCCESS);
    }
```

NAME

makedev, major, minor − manage a device number

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/sysmacros.h>

dev_t makedev(unsigned int *maj***, unsigned int** *min***);**

unsigned int major(dev_t *dev***);**
unsigned int minor(dev_t *dev***);**

DESCRIPTION

A device ID consists of two parts: a major ID, identifying the class of the device, and a minor ID, identifying a specific instance of a device in that class. A device ID is represented using the type *dev_t*.

Given major and minor device IDs, **makedev**() combines these to produce a device ID, returned as the function result. This device ID can be given to *mknod*(2), for example.

The **major**() and **minor**() functions perform the converse task: given a device ID, they return, respectively, the major and minor components. These macros can be useful to, for example, decompose the device IDs in the structure returned by *stat*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
makedev(), **major**(), **minor**()	Thread safety	MT-Safe

VERSIONS

The BSDs expose the definitions for these macros via <*sys/types.h*>.

STANDARDS

None.

HISTORY

BSD, HP-UX, Solaris, AIX, Irix.

These interfaces are defined as macros. Since glibc 2.3.3, they have been aliases for three GNU-specific functions: **gnu_dev_makedev**(), **gnu_dev_major**(), and **gnu_dev_minor**(). The latter names are exported, but the traditional names are more portable.

Depending on the version, glibc also exposes definitions for these macros from <*sys/types.h*> if suitable feature test macros are defined. However, this behavior was deprecated in glibc 2.25, and since glibc 2.28, <*sys/types.h*> no longer provides these definitions.

SEE ALSO

mknod(2), *stat*(2)

NAME

mallinfo, mallinfo2 − obtain memory allocation information

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

struct mallinfo mallinfo(void);
struct mallinfo2 mallinfo2(void);

DESCRIPTION

These functions return a copy of a structure containing information about memory allocations performed by *malloc*(3) and related functions. The structure returned by each function contains the same fields. However, the older function, **mallinfo**(), is deprecated since the type used for the fields is too small (see BUGS).

Note that not all allocations are visible to these functions; see BUGS and consider using *malloc_info*(3) instead.

The *mallinfo2* structure returned by **mallinfo2**() is defined as follows:

```
struct mallinfo2 {
    size_t arena;     /* Non-mmapped space allocated (bytes) */
    size_t ordblks;   /* Number of free chunks */
    size_t smblks;    /* Number of free fastbin blocks */
    size_t hblks;     /* Number of mmapped regions */
    size_t hblkhd;    /* Space allocated in mmapped regions
                         (bytes) */
    size_t usmblks;   /* See below */
    size_t fsmblks;   /* Space in freed fastbin blocks (bytes) */
    size_t uordblks;  /* Total allocated space (bytes) */
    size_t fordblks;  /* Total free space (bytes) */
    size_t keepcost;  /* Top-most, releasable space (bytes) */
};
```

The *mallinfo* structure returned by the deprecated **mallinfo**() function is exactly the same, except that the fields are typed as *int*.

The structure fields contain the following information:

arena The total amount of memory allocated by means other than *mmap*(2) (i.e., memory allocated on the heap). This figure includes both in-use blocks and blocks on the free list.

ordblks The number of ordinary (i.e., non-fastbin) free blocks.

smblks The number of fastbin free blocks (see *mallopt*(3)).

hblks The number of blocks currently allocated using *mmap*(2). (See the discussion of **M_MMAP_THRESHOLD** in *mallopt*(3).)

hblkhd The number of bytes in blocks currently allocated using *mmap*(2).

usmblks This field is unused, and is always 0. Historically, it was the "highwater mark" for allocated space—that is, the maximum amount of space that was ever allocated (in bytes); this field was maintained only in nonthreading environments.

fsmblks The total number of bytes in fastbin free blocks.

uordblks The total number of bytes used by in-use allocations.

fordblks The total number of bytes in free blocks.

keepcost The total amount of releasable free space at the top of the heap. This is the maximum number of bytes that could ideally (i.e., ignoring page alignment restrictions, and so on) be released by *malloc_trim*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mallinfo(), **mallinfo2**()	Thread safety	MT-Unsafe init const:mallopt

mallinfo()/ **mallinfo2**() would access some global internal objects. If modify them with non-atomically, may get inconsistent results. The identifier *mallopt* in *const:mallopt* mean that **mallopt**() would modify the global internal objects with atomics, that make sure **mallinfo**()/ **mallinfo2**() is safe enough, others modify with non-atomically maybe not.

STANDARDS

None.

HISTORY

mallinfo()

glibc 2.0. SVID.

mallinfo2()

glibc 2.33.

BUGS

Information is returned for only the main memory allocation area. Allocations in other arenas are excluded. See *malloc_stats*(3) and *malloc_info*(3) for alternatives that include information about other arenas.

The fields of the *mallinfo* structure that is returned by the older **mallinfo**() function are typed as *int*. However, because some internal bookkeeping values may be of type *long*, the reported values may wrap around zero and thus be inaccurate.

EXAMPLES

The program below employs **mallinfo2**() to retrieve memory allocation statistics before and after allocating and freeing some blocks of memory. The statistics are displayed on standard output.

The first two command-line arguments specify the number and size of blocks to be allocated with *malloc*(3).

The remaining three arguments specify which of the allocated blocks should be freed with *free*(3). These three arguments are optional, and specify (in order): the step size to be used in the loop that frees blocks (the default is 1, meaning free all blocks in the range); the ordinal position of the first block to be freed (default 0, meaning the first allocated block); and a number one greater than the ordinal position of the last block to be freed (default is one greater than the maximum block number). If these three arguments are omitted, then the defaults cause all allocated blocks to be freed.

In the following example run of the program, 1000 allocations of 100 bytes are performed, and then every second allocated block is freed:

```
$ ./a.out 1000 100 2
============== Before allocating blocks ==============
Total non-mmapped bytes (arena):       0
# of free chunks (ordblks):            1
# of free fastbin blocks (smblks):     0
# of mapped regions (hblks):           0
Bytes in mapped regions (hblkhd):      0
Max. total allocated space (usmblks):  0
Free bytes held in fastbins (fsmblks): 0
Total allocated space (uordblks):      0

NAME

malloc, free, calloc, realloc, reallocarray − allocate and free dynamic memory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

void *malloc(size_t size);
void free(void *_Nullable ptr);
void *calloc(size_t nmemb, size_t size);
void *realloc(void *_Nullable ptr, size_t size);
void *reallocarray(void *_Nullable ptr, size_t nmemb, size_t size);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

reallocarray():
Since glibc 2.29:
_DEFAULT_SOURCE
glibc 2.28 and earlier:
_GNU_SOURCE

DESCRIPTION

malloc()

The **malloc**() function allocates *size* bytes and returns a pointer to the allocated memory. *The memory is not initialized*. If *size* is 0, then **malloc**() returns a unique pointer value that can later be successfully passed to **free**(). (See "Nonportable behavior" for portability issues.)

free()

The **free**() function frees the memory space pointed to by *ptr*, which must have been returned by a previous call to **malloc**() or related functions. Otherwise, or if *ptr* has already been freed, undefined behavior occurs. If *ptr* is NULL, no operation is performed.

calloc()

The **calloc**() function allocates memory for an array of *nmemb* elements of *size* bytes each and returns a pointer to the allocated memory. The memory is set to zero. If *nmemb* or *size* is 0, then **calloc**() returns a unique pointer value that can later be successfully passed to **free**().

If the multiplication of *nmemb* and *size* would result in integer overflow, then **calloc**() returns an error. By contrast, an integer overflow would not be detected in the following call to **malloc**(), with the result that an incorrectly sized block of memory would be allocated:

```
malloc(nmemb * size);
```

realloc()

The **realloc**() function changes the size of the memory block pointed to by *ptr* to *size* bytes. The contents of the memory will be unchanged in the range from the start of the region up to the minimum of the old and new sizes. If the new size is larger than the old size, the added memory will *not* be initialized.

If *ptr* is NULL, then the call is equivalent to *malloc(size)*, for all values of *size*.

If *size* is equal to zero, and *ptr* is not NULL, then the call is equivalent to *free(ptr)* (but see "Nonportable behavior" for portability issues).

Unless *ptr* is NULL, it must have been returned by an earlier call to **malloc** or related functions. If the area pointed to was moved, a *free(ptr)* is done.

reallocarray()

The **reallocarray**() function changes the size of (and possibly moves) the memory block pointed to by *ptr* to be large enough for an array of *nmemb* elements, each of which is *size* bytes. It is equivalent to the call

```
realloc(ptr, nmemb * size);
```

However, unlike that **realloc**() call, **reallocarray**() fails safely in the case where the multiplication would overflow. If such an overflow occurs, **reallocarray**() returns an error.

RETURN VALUE

The **malloc**(), **calloc**(), **realloc**(), and **reallocarray**() functions return a pointer to the allocated memory, which is suitably aligned for any type that fits into the requested size or less. On error, these functions return NULL and set *errno*. Attempting to allocate more than **PTRDIFF_MAX** bytes is considered an error, as an object that large could cause later pointer subtraction to overflow.

The **free**() function returns no value, and preserves *errno*.

The **realloc**() and **reallocarray**() functions return NULL if *ptr* is not NULL and the requested size is zero; this is not considered an error. (See "Nonportable behavior" for portability issues.) Otherwise, the returned pointer may be the same as *ptr* if the allocation was not moved (e.g., there was room to expand the allocation in-place), or different from *ptr* if the allocation was moved to a new address. If these functions fail, the original block is left untouched; it is not freed or moved.

ERRORS

calloc(), **malloc**(), **realloc**(), and **reallocarray**() can fail with the following error:

ENOMEM
Out of memory. Possibly, the application hit the **RLIMIT_AS** or **RLIMIT_DATA** limit described in *getrlimit*(2). Another reason could be that the number of mappings created by the caller process exceeded the limit specified by */proc/sys/vm/max_map_count*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
malloc(), **free**(), **calloc**(), **realloc**()	Thread safety	MT-Safe

STANDARDS

malloc()
free()
calloc()
realloc()
C11, POSIX.1-2008.

reallocarray()
None.

HISTORY

malloc()
free()
calloc()
realloc()
POSIX.1-2001, C89.

reallocarray()
glibc 2.26. OpenBSD 5.6, FreeBSD 11.0.

malloc() and related functions rejected sizes greater than **PTRDIFF_MAX** starting in glibc 2.30.

free() preserved *errno* starting in glibc 2.33.

NOTES

By default, Linux follows an optimistic memory allocation strategy. This means that when **malloc**() returns non-NULL there is no guarantee that the memory really is available. In case it turns out that the system is out of memory, one or more processes will be killed by the OOM killer. For more information, see the description of */proc/sys/vm/overcommit_memory* and */proc/sys/vm/oom_adj* in *proc*(5), and the Linux kernel source file *Documentation/vm/overcommit−accounting.rst*.

Normally, **malloc**() allocates memory from the heap, and adjusts the size of the heap as required, using *sbrk*(2). When allocating blocks of memory larger than **MMAP_THRESHOLD** bytes, the glibc **malloc**() implementation allocates the memory as a private anonymous mapping using *mmap*(2). **MMAP_THRESHOLD** is 128 kB by default, but is adjustable using *mallopt*(3). Prior to Linux 4.7 allocations performed using *mmap*(2) were unaffected by the **RLIMIT_DATA** resource limit; since Linux 4.7, this limit is also enforced for allocations performed using *mmap*(2).

To avoid corruption in multithreaded applications, mutexes are used internally to protect the memory-management data structures employed by these functions. In a multithreaded application in which

threads simultaneously allocate and free memory, there could be contention for these mutexes. To scalably handle memory allocation in multithreaded applications, glibc creates additional *memory allocation arenas* if mutex contention is detected. Each arena is a large region of memory that is internally allocated by the system (using *brk*(2) or *mmap*(2)), and managed with its own mutexes.

If your program uses a private memory allocator, it should do so by replacing **malloc**(), **free**(), **calloc**(), and **realloc**(). The replacement functions must implement the documented glibc behaviors, including *errno* handling, size-zero allocations, and overflow checking; otherwise, other library routines may crash or operate incorrectly. For example, if the replacement *free*() does not preserve *errno*, then seemingly unrelated library routines may fail without having a valid reason in *errno*. Private memory allocators may also need to replace other glibc functions; see "Replacing malloc" in the glibc manual for details.

Crashes in memory allocators are almost always related to heap corruption, such as overflowing an allocated chunk or freeing the same pointer twice.

The **malloc**() implementation is tunable via environment variables; see *mallopt*(3) for details.

Nonportable behavior

The behavior of these functions when the requested size is zero is glibc specific; other implementations may return NULL without setting *errno*, and portable POSIX programs should tolerate such behavior. See *realloc*(3p)

POSIX requires memory allocators to set *errno* upon failure. However, the C standard does not require this, and applications portable to non-POSIX platforms should not assume this.

Portable programs should not use private memory allocators, as POSIX and the C standard do not allow replacement of **malloc**(), **free**(), **calloc**(), and **realloc**().

EXAMPLES

```
#include <err.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define MALLOCARRAY(n, type)  ((type *) my_mallocarray(n, sizeof(type)))
#define MALLOC(type)          MALLOCARRAY(1, type)

static inline void *my_mallocarray(size_t nmemb, size_t size);

int
main(void)
{
    char  *p;

    p = MALLOCARRAY(32, char);
    if (p == NULL)
        err(EXIT_FAILURE, "malloc");

    strlcpy(p, "foo", 32);
    puts(p);
}

static inline void *
my_mallocarray(size_t nmemb, size_t size)
{
    return reallocarray(NULL, nmemb, size);
}
```

NAME

malloc_get_state, malloc_set_state − record and restore state of malloc implementation

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

void *malloc_get_state(void);
int malloc_set_state(void *_state_);

DESCRIPTION

Note: these functions are removed in glibc 2.25.

The **malloc_get_state**() function records the current state of all *malloc*(3) internal bookkeeping variables (but not the actual contents of the heap or the state of *malloc_hook*(3) functions pointers). The state is recorded in a system-dependent opaque data structure dynamically allocated via *malloc*(3), and a pointer to that data structure is returned as the function result. (It is the caller's responsibility to *free*(3) this memory.)

The **malloc_set_state**() function restores the state of all *malloc*(3) internal bookkeeping variables to the values recorded in the opaque data structure pointed to by *state*.

RETURN VALUE

On success, **malloc_get_state**() returns a pointer to a newly allocated opaque data structure. On error (for example, memory could not be allocated for the data structure), **malloc_get_state**() returns NULL.

On success, **malloc_set_state**() returns 0. If the implementation detects that *state* does not point to a correctly formed data structure, **malloc_set_state**() returns −1. If the implementation detects that the version of the data structure referred to by *state* is a more recent version than this implementation knows about, **malloc_set_state**() returns −2.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
malloc_get_state(), **malloc_set_state**()	Thread safety	MT-Safe

STANDARDS

GNU.

NOTES

These functions are useful when using this *malloc*(3) implementation as part of a shared library, and the heap contents are saved/restored via some other method. This technique is used by GNU Emacs to implement its "dumping" function.

Hook function pointers are never saved or restored by these functions, with two exceptions: if malloc checking (see *mallopt*(3)) was in use when **malloc_get_state**() was called, then **malloc_set_state**() resets malloc checking hooks if possible; if malloc checking was not in use in the recorded state, but the caller has requested malloc checking, then the hooks are reset to 0.

malloc(3), *mallopt*(3)

NAME

__malloc_hook, __malloc_initialize_hook, __memalign_hook, __free_hook, __realloc_hook, __after_morecore_hook − malloc debugging variables (DEPRECATED)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <malloc.h>

void *(*volatile __malloc_hook)(size_t size, const void *caller);

void *(*volatile __realloc_hook)(void *ptr, size_t size,
                                 const void *caller);

void *(*volatile __memalign_hook)(size_t alignment, size_t size,
                                  const void *caller);

void (*volatile __free_hook)(void *ptr, const void *caller);

void (*__malloc_initialize_hook)(void);

void (*volatile __after_morecore_hook)(void);
```

DESCRIPTION

The GNU C library lets you modify the behavior of *malloc*(3), *realloc*(3), and *free*(3) by specifying appropriate hook functions. You can use these hooks to help you debug programs that use dynamic memory allocation, for example.

The variable **__malloc_initialize_hook** points at a function that is called once when the malloc implementation is initialized. This is a weak variable, so it can be overridden in the application with a definition like the following:

```
void (*__malloc_initialize_hook)(void) = my_init_hook;
```

Now the function *my_init_hook*() can do the initialization of all hooks.

The four functions pointed to by **__malloc_hook**, **__realloc_hook**, **__memalign_hook**, **__free_hook** have a prototype like the functions *malloc*(3), *realloc*(3), *memalign*(3), *free*(3), respectively, except that they have a final argument *caller* that gives the address of the caller of *malloc*(3), etc.

The variable **__after_morecore_hook** points at a function that is called each time after *sbrk*(2) was asked for more memory.

STANDARDS

GNU.

NOTES

The use of these hook functions is not safe in multithreaded programs, and they are now deprecated. From glibc 2.24 onwards, the **__malloc_initialize_hook** variable has been removed from the API, and from glibc 2.34 onwards, all the hook variables have been removed from the API. Programmers should instead preempt calls to the relevant functions by defining and exporting **malloc**(), **free**(), **realloc**(), and **calloc**().

EXAMPLES

Here is a short example of how to use these variables.

```
#include <stdio.h>
#include <malloc.h>

/* Prototypes for our hooks */
static void my_init_hook(void);
static void *my_malloc_hook(size_t, const void *);

/* Variables to save original hooks */
static void *(*old_malloc_hook)(size_t, const void *);

/* Override initializing hook from the C library */
void (*__malloc_initialize_hook)(void) = my_init_hook;
```

```
static void
my_init_hook(void)
{
    old_malloc_hook = __malloc_hook;
    __malloc_hook = my_malloc_hook;
}

static void *
my_malloc_hook(size_t size, const void *caller)
{
    void *result;

    /* Restore all old hooks */
    __malloc_hook = old_malloc_hook;

    /* Call recursively */
    result = malloc(size);

    /* Save underlying hooks */
    old_malloc_hook = __malloc_hook;

    /* printf() might call malloc(), so protect it too */
    printf("malloc(%zu) called from %p returns %p\n",
            size, caller, result);

    /* Restore our own hooks */
    __malloc_hook = my_malloc_hook;

    return result;
}
```

mallinfo(3), *malloc*(3), *mcheck*(3), *mtrace*(3)

NAME

malloc_info − export malloc state to a stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

int malloc_info(int *options***, FILE ****stream***);**

DESCRIPTION

The **malloc_info**() function exports an XML string that describes the current state of the memory-allocation implementation in the caller. The string is printed on the file stream *stream*. The exported string includes information about all arenas (see *malloc*(3)).

As currently implemented, *options* must be zero.

RETURN VALUE

On success, **malloc_info**() returns 0. On failure, it returns −1, and *errno* is set to indicate the error.

ERRORS

EINVAL

options was nonzero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
malloc_info()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.10.

NOTES

The memory-allocation information is provided as an XML string (rather than a C structure) because the information may change over time (according to changes in the underlying implementation). The output XML string includes a version field.

The *open_memstream*(3) function can be used to send the output of **malloc_info**() directly into a buffer in memory, rather than to a file.

The **malloc_info**() function is designed to address deficiencies in *malloc_stats*(3) and *mallinfo*(3).

EXAMPLES

The program below takes up to four command-line arguments, of which the first three are mandatory. The first argument specifies the number of threads that the program should create. All of the threads, including the main thread, allocate the number of blocks of memory specified by the second argument. The third argument controls the size of the blocks to be allocated. The main thread creates blocks of this size, the second thread created by the program allocates blocks of twice this size, the third thread allocates blocks of three times this size, and so on.

The program calls **malloc_info**() twice to display the memory-allocation state. The first call takes place before any threads are created or memory allocated. The second call is performed after all threads have allocated memory.

In the following example, the command-line arguments specify the creation of one additional thread, and both the main thread and the additional thread allocate 10000 blocks of memory. After the blocks of memory have been allocated, **malloc_info**() shows the state of two allocation arenas.

```

NAME

malloc_stats − print memory allocation statistics

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

void malloc_stats(void);

DESCRIPTION

The **malloc_stats**() function prints (on standard error) statistics about memory allocated by *malloc*(3) and related functions. For each arena (allocation area), this function prints the total amount of memory allocated and the total number of bytes consumed by in-use allocations. (These two values correspond to the *arena* and *uordblks* fields retrieved by *mallinfo*(3).) In addition, the function prints the sum of these two statistics for all arenas, and the maximum number of blocks and bytes that were ever simultaneously allocated using *mmap*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
malloc_stats()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.0.

NOTES

More detailed information about memory allocations in the main arena can be obtained using *mallinfo*(3).

NAME

malloc_trim − release free memory from the heap

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

int malloc_trim(size_t *pad***);**

DESCRIPTION

The **malloc_trim**() function attempts to release free memory from the heap (by calling *sbrk*(2) or *madvise*(2) with suitable arguments).

The *pad* argument specifies the amount of free space to leave untrimmed at the top of the heap. If this argument is 0, only the minimum amount of memory is maintained at the top of the heap (i.e., one page or less). A nonzero argument can be used to maintain some trailing space at the top of the heap in order to allow future allocations to be made without having to extend the heap with *sbrk*(2).

RETURN VALUE

The **malloc_trim**() function returns 1 if memory was actually released back to the system, or 0 if it was not possible to release any memory.

ERRORS

No errors are defined.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
malloc_trim()	Thread safety	MT-Safe

STANDARDS

GNU.

VERSIONS

glibc 2.0.

NOTES

Only the main heap (using *sbrk*(2)) honors the *pad* argument; thread heaps do not.

Since glibc 2.8 this function frees memory in all arenas and in all chunks with whole free pages.

Before glibc 2.8 this function only freed memory at the top of the heap in the main arena.

SEE ALSO

sbrk(2), *malloc*(3), *mallopt*(3)

NAME

malloc_usable_size − obtain size of block of memory allocated from heap

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

size_t malloc_usable_size(void *_Nullable *ptr***);**

DESCRIPTION

This function can be used for diagnostics or statistics about allocations from *malloc*(3) or a related function.

RETURN VALUE

malloc_usable_size() returns a value no less than the size of the block of allocated memory pointed to by *ptr*. If *ptr* is NULL, 0 is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
malloc_usable_size()	Thread safety	MT-Safe

STANDARDS

GNU.

CAVEATS

The value returned by **malloc_usable_size**() may be greater than the requested size of the allocation because of various internal implementation details, none of which the programmer should rely on. This function is intended to only be used for diagnostics and statistics; writing to the excess memory without first calling *realloc*(3) to resize the allocation is not supported. The returned value is only valid at the time of the call.

SEE ALSO

malloc(3)

NAME

mallopt − set memory allocation parameters

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <malloc.h>

int mallopt(int *param***, int** *value***);**

DESCRIPTION

The **mallopt**() function adjusts parameters that control the behavior of the memory-allocation functions (see *malloc*(3)). The *param* argument specifies the parameter to be modified, and *value* specifies the new value for that parameter.

The following values can be specified for *param*:

M_ARENA_MAX

If this parameter has a nonzero value, it defines a hard limit on the maximum number of arenas that can be created. An arena represents a pool of memory that can be used by *malloc*(3) (and similar) calls to service allocation requests. Arenas are thread safe and therefore may have multiple concurrent memory requests. The trade-off is between the number of threads and the number of arenas. The more arenas you have, the lower the per-thread contention, but the higher the memory usage.

The default value of this parameter is 0, meaning that the limit on the number of arenas is determined according to the setting of **M_ARENA_TEST**.

This parameter has been available since glibc 2.10 via **--enable-experimental-malloc**, and since glibc 2.15 by default. In some versions of the allocator there was no limit on the number of created arenas (e.g., CentOS 5, RHEL 5).

When employing newer glibc versions, applications may in some cases exhibit high contention when accessing arenas. In these cases, it may be beneficial to increase **M_ARENA_MAX** to match the number of threads. This is similar in behavior to strategies taken by tcmalloc and jemalloc (e.g., per-thread allocation pools).

M_ARENA_TEST

This parameter specifies a value, in number of arenas created, at which point the system configuration will be examined to determine a hard limit on the number of created arenas. (See **M_ARENA_MAX** for the definition of an arena.)

The computation of the arena hard limit is implementation-defined and is usually calculated as a multiple of the number of available CPUs. Once the hard limit is computed, the result is final and constrains the total number of arenas.

The default value for the **M_ARENA_TEST** parameter is 2 on systems where *sizeof(long)* is 4; otherwise the default value is 8.

This parameter has been available since glibc 2.10 via **--enable-experimental-malloc**, and since glibc 2.15 by default.

The value of **M_ARENA_TEST** is not used when **M_ARENA_MAX** has a nonzero value.

M_CHECK_ACTION

Setting this parameter controls how glibc responds when various kinds of programming errors are detected (e.g., freeing the same pointer twice). The 3 least significant bits (2, 1, and 0) of the value assigned to this parameter determine the glibc behavior, as follows:

Bit 0 If this bit is set, then print a one-line message on *stderr* that provides details about the error. The message starts with the string "*** glibc detected ***", followed by the program name, the name of the memory-allocation function in which the error was detected, a brief description of the error, and the memory address where the error was detected.

Bit 1 If this bit is set, then, after printing any error message specified by bit 0, the program is terminated by calling *abort*(3). Since glibc 2.4, if bit 0 is also set, then, between printing the error message and aborting, the program also prints a stack trace in the

manner of *backtrace*(3), and prints the process's memory mapping in the style of */proc/*pid*/maps* (see *proc*(5)).

Bit 2 (since glibc 2.4)
: This bit has an effect only if bit 0 is also set. If this bit is set, then the one-line message describing the error is simplified to contain just the name of the function where the error was detected and the brief description of the error.

The remaining bits in *value* are ignored.

Combining the above details, the following numeric values are meaningful for **M_CHECK_ACTION**:

0 Ignore error conditions; continue execution (with undefined results).

1 Print a detailed error message and continue execution.

2 Abort the program.

3 Print detailed error message, stack trace, and memory mappings, and abort the program.

5 Print a simple error message and continue execution.

7 Print simple error message, stack trace, and memory mappings, and abort the program.

Since glibc 2.3.4, the default value for the **M_CHECK_ACTION** parameter is 3. In glibc 2.3.3 and earlier, the default value is 1.

Using a nonzero **M_CHECK_ACTION** value can be useful because otherwise a crash may happen much later, and the true cause of the problem is then very hard to track down.

M_MMAP_MAX
: This parameter specifies the maximum number of allocation requests that may be simultaneously serviced using *mmap*(2). This parameter exists because some systems have a limited number of internal tables for use by *mmap*(2), and using more than a few of them may degrade performance.

The default value is 65,536, a value which has no special significance and which serves only as a safeguard. Setting this parameter to 0 disables the use of *mmap*(2) for servicing large allocation requests.

M_MMAP_THRESHOLD
: For allocations greater than or equal to the limit specified (in bytes) by **M_MMAP_THRESHOLD** that can't be satisfied from the free list, the memory-allocation functions employ *mmap*(2) instead of increasing the program break using *sbrk*(2).

Allocating memory using *mmap*(2) has the significant advantage that the allocated memory blocks can always be independently released back to the system. (By contrast, the heap can be trimmed only if memory is freed at the top end.) On the other hand, there are some disadvantages to the use of *mmap*(2): deallocated space is not placed on the free list for reuse by later allocations; memory may be wasted because *mmap*(2) allocations must be page-aligned; and the kernel must perform the expensive task of zeroing out memory allocated via *mmap*(2). Balancing these factors leads to a default setting of 128*1024 for the **M_MMAP_THRESHOLD** parameter.

The lower limit for this parameter is 0. The upper limit is **DEFAULT_MMAP_THRESHOLD_MAX**: 512*1024 on 32-bit systems or *4*1024*1024*sizeof(long)* on 64-bit systems.

Note: Nowadays, glibc uses a dynamic mmap threshold by default. The initial value of the threshold is 128*1024, but when blocks larger than the current threshold and less than or equal to **DEFAULT_MMAP_THRESHOLD_MAX** are freed, the threshold is adjusted upward to the size of the freed block. When dynamic mmap thresholding is in effect, the threshold for trimming the heap is also dynamically adjusted to be twice the dynamic mmap threshold. Dynamic adjustment of the mmap threshold is disabled if any of the **M_TRIM_THRESHOLD**, **M_TOP_PAD**, **M_MMAP_THRESHOLD**, or **M_MMAP_MAX** parameters is set.

M_MXFAST (since glibc 2.3)
Set the upper limit for memory allocation requests that are satisfied using "fastbins". (The measurement unit for this parameter is bytes.) Fastbins are storage areas that hold deallocated blocks of memory of the same size without merging adjacent free blocks. Subsequent reallocation of blocks of the same size can be handled very quickly by allocating from the fastbin, although memory fragmentation and the overall memory footprint of the program can increase.

The default value for this parameter is *64*sizeof(size_t)/4* (i.e., 64 on 32-bit architectures). The range for this parameter is 0 to *80*sizeof(size_t)/4*. Setting **M_MXFAST** to 0 disables the use of fastbins.

M_PERTURB (since glibc 2.4)
If this parameter is set to a nonzero value, then bytes of allocated memory (other than allocations via *calloc*(3)) are initialized to the complement of the value in the least significant byte of *value*, and when allocated memory is released using *free*(3), the freed bytes are set to the least significant byte of *value*. This can be useful for detecting errors where programs incorrectly rely on allocated memory being initialized to zero, or reuse values in memory that has already been freed.

The default value for this parameter is 0.

M_TOP_PAD
This parameter defines the amount of padding to employ when calling *sbrk*(2) to modify the program break. (The measurement unit for this parameter is bytes.) This parameter has an effect in the following circumstances:

- When the program break is increased, then **M_TOP_PAD** bytes are added to the *sbrk*(2) request.
- When the heap is trimmed as a consequence of calling *free*(3) (see the discussion of **M_TRIM_THRESHOLD**) this much free space is preserved at the top of the heap.

In either case, the amount of padding is always rounded to a system page boundary.

Modifying **M_TOP_PAD** is a trade-off between increasing the number of system calls (when the parameter is set low) and wasting unused memory at the top of the heap (when the parameter is set high).

The default value for this parameter is 128*1024.

M_TRIM_THRESHOLD
When the amount of contiguous free memory at the top of the heap grows sufficiently large, *free*(3) employs *sbrk*(2) to release this memory back to the system. (This can be useful in programs that continue to execute for a long period after freeing a significant amount of memory.) The **M_TRIM_THRESHOLD** parameter specifies the minimum size (in bytes) that this block of memory must reach before *sbrk*(2) is used to trim the heap.

The default value for this parameter is 128*1024. Setting **M_TRIM_THRESHOLD** to −1 disables trimming completely.

Modifying **M_TRIM_THRESHOLD** is a trade-off between increasing the number of system calls (when the parameter is set low) and wasting unused memory at the top of the heap (when the parameter is set high).

Environment variables

A number of environment variables can be defined to modify some of the same parameters as are controlled by **mallopt**(). Using these variables has the advantage that the source code of the program need not be changed. To be effective, these variables must be defined before the first call to a memory-allocation function. (If the same parameters are adjusted via **mallopt**(), then the **mallopt**() settings take precedence.) For security reasons, these variables are ignored in set-user-ID and set-group-ID programs.

The environment variables are as follows (note the trailing underscore at the end of the name of some variables):

MALLOC_ARENA_MAX
Controls the same parameter as **mallopt**() **M_ARENA_MAX**.

MALLOC_ARENA_TEST
Controls the same parameter as **mallopt**() **M_ARENA_TEST**.

MALLOC_CHECK_
This environment variable controls the same parameter as **mallopt**() **M_CHECK_ACTION**. If this variable is set to a nonzero value, then a special implementation of the memory-allocation functions is used. (This is accomplished using the *malloc_hook*(3) feature.) This implementation performs additional error checking, but is slower than the standard set of memory-allocation functions. (This implementation does not detect all possible errors; memory leaks can still occur.)

The value assigned to this environment variable should be a single digit, whose meaning is as described for **M_CHECK_ACTION**. Any characters beyond the initial digit are ignored.

For security reasons, the effect of **MALLOC_CHECK_** is disabled by default for set-user-ID and set-group-ID programs. However, if the file */etc/suid−debug* exists (the content of the file is irrelevant), then **MALLOC_CHECK_** also has an effect for set-user-ID and set-group-ID programs.

MALLOC_MMAP_MAX_
Controls the same parameter as **mallopt**() **M_MMAP_MAX**.

MALLOC_MMAP_THRESHOLD_
Controls the same parameter as **mallopt**() **M_MMAP_THRESHOLD**.

MALLOC_PERTURB_
Controls the same parameter as **mallopt**() **M_PERTURB**.

MALLOC_TRIM_THRESHOLD_
Controls the same parameter as **mallopt**() **M_TRIM_THRESHOLD**.

MALLOC_TOP_PAD_
Controls the same parameter as **mallopt**() **M_TOP_PAD**.

RETURN VALUE

On success, **mallopt**() returns 1. On error, it returns 0.

ERRORS

On error, *errno* is *not* set.

VERSIONS

A similar function exists on many System V derivatives, but the range of values for *param* varies across systems. The SVID defined options **M_MXFAST**, **M_NLBLKS**, **M_GRAIN**, and **M_KEEP**, but only the first of these is implemented in glibc.

STANDARDS

None.

HISTORY

glibc 2.0.

BUGS

Specifying an invalid value for *param* does not generate an error.

A calculation error within the glibc implementation means that a call of the form:

```
mallopt(M_MXFAST, n)
```

does not result in fastbins being employed for all allocations of size up to *n*. To ensure desired results, *n* should be rounded up to the next multiple greater than or equal to *(2k+1)*sizeof(size_t)*, where *k* is an integer.

If **mallopt**() is used to set **M_PERTURB**, then, as expected, the bytes of allocated memory are initialized to the complement of the byte in *value*, and when that memory is freed, the bytes of the region are initialized to the byte specified in *value*. However, there is an off-by-*sizeof(size_t)* error in the implementation: instead of initializing precisely the block of memory being freed by the call *free(p)*, the block starting at *p+sizeof(size_t)* is initialized.

EXAMPLES

The program below demonstrates the use of **M_CHECK_ACTION**. If the program is supplied with an (integer) command-line argument, then that argument is used to set the **M_CHECK_ACTION** parameter. The program then allocates a block of memory, and frees it twice (an error).

The following shell session shows what happens when we run this program under glibc, with the default value for **M_CHECK_ACTION**:

```
$ ./a.out
main(): returned from first free() call
*** glibc detected *** ./a.out: double free or corruption (top): 0x09d30008 ***
======= Backtrace: =========
/lib/libc.so.6(+0x6c501)[0x523501]
/lib/libc.so.6(+0x6dd70)[0x524d70]
/lib/libc.so.6(cfree+0x6d)[0x527e5d]
./a.out[0x80485db]
/lib/libc.so.6(__libc_start_main+0xe7)[0x4cdce7]
./a.out[0x8048471]
======= Memory map: ========
001e4000-001fe000 r-xp 00000000 08:06 1083555    /lib/libgcc_s.so.1
001fe000-001ff000 r--p 00019000 08:06 1083555    /lib/libgcc_s.so.1

bff53000-bff74000 rw-p 00000000 00:00 0          [stack]
Aborted (core dumped)
```

The following runs show the results when employing other values for **M_CHECK_ACTION**:

```
$ ./a.out 1             # Diagnose error and continue
main(): returned from first free() call
*** glibc detected *** ./a.out: double free or corruption (top): 0x09cbe008 ***
main(): returned from second free() call
$ ./a.out 2             # Abort without error message
main(): returned from first free() call
Aborted (core dumped)
$ ./a.out 0             # Ignore error and continue
main(): returned from first free() call
main(): returned from second free() call
```

The next run shows how to set the same parameter using the **MALLOC_CHECK_** environment variable:

```
$ MALLOC_CHECK_=1 ./a.out
main(): returned from first free() call
*** glibc detected *** ./a.out: free(): invalid pointer: 0x092c2008 ***
main(): returned from second free() call
```

Program source

```
#include <malloc.h>
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
{
    char *p;

    if (argc > 1) {
        if (mallopt(M_CHECK_ACTION, atoi(argv[1])) != 1) {
            fprintf(stderr, "mallopt() failed");
            exit(EXIT_FAILURE);
        }
```

```
        }

        p = malloc(1000);
        if (p == NULL) {
            fprintf(stderr, "malloc() failed");
            exit(EXIT_FAILURE);
        }

        free(p);
        printf("%s(): returned from first free() call\n", __func__);

        free(p);
        printf("%s(): returned from second free() call\n", __func__);

        exit(EXIT_SUCCESS);
    }
```

NAME

matherr − SVID math library exception handling

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <math.h>

[[deprecated]] int matherr(struct exception *****exc*);**

[[deprecated]] extern _LIB_VERSION_TYPE _LIB_VERSION;

DESCRIPTION

Note: the mechanism described in this page is no longer supported by glibc. Before glibc 2.27, it had been marked as obsolete. Since glibc 2.27, the mechanism has been removed altogether. New applications should use the techniques described in *math_error*(7) and *fenv*(3). This page documents the **matherr**() mechanism as an aid for maintaining and porting older applications.

The System V Interface Definition (SVID) specifies that various math functions should invoke a function called **matherr**() if a math exception is detected. This function is called before the math function returns; after **matherr**() returns, the system then returns to the math function, which in turn returns to the caller.

To employ **matherr**(), the programmer must define the **_SVID_SOURCE** feature test macro (before including *any* header files), and assign the value **_SVID_** to the external variable **_LIB_VERSION**.

The system provides a default version of **matherr**(). This version does nothing, and returns zero (see below for the significance of this). The default **matherr**() can be overridden by a programmer-defined version, which will be invoked when an exception occurs. The function is invoked with one argument, a pointer to an *exception* structure, defined as follows:

```
struct exception {
    int    type;      /* Exception type */
    char  *name;      /* Name of function causing exception */
    double arg1;      /* 1st argument to function */
    double arg2;      /* 2nd argument to function */
    double retval;    /* Function return value */
}
```

The *type* field has one of the following values:

DOMAIN A domain error occurred (the function argument was outside the range for which the function is defined). The return value depends on the function; *errno* is set to **EDOM**.

SING A pole error occurred (the function result is an infinity). The return value in most cases is **HUGE** (the largest single precision floating-point number), appropriately signed. In most cases, *errno* is set to **EDOM**.

OVERFLOW
An overflow occurred. In most cases, the value **HUGE** is returned, and *errno* is set to **ERANGE**.

UNDERFLOW
An underflow occurred. 0.0 is returned, and *errno* is set to **ERANGE**.

TLOSS Total loss of significance. 0.0 is returned, and *errno* is set to **ERANGE**.

PLOSS Partial loss of significance. This value is unused on glibc (and many other systems).

The *arg1* and *arg2* fields are the arguments supplied to the function (*arg2* is undefined for functions that take only one argument).

The *retval* field specifies the return value that the math function will return to its caller. The programmer-defined **matherr**() can modify this field to change the return value of the math function.

If the **matherr**() function returns zero, then the system sets *errno* as described above, and may print an error message on standard error (see below).

If the **matherr**() function returns a nonzero value, then the system does not set *errno*, and doesn't print an error message.

Math functions that employ matherr()

The table below lists the functions and circumstances in which **matherr**() is called. The "Type" column indicates the value assigned to *exc−>type* when calling **matherr**(). The "Result" column is the default return value assigned to *exc−>retval*.

The "Msg?" and "errno" columns describe the default behavior if **matherr**() returns zero. If the "Msg?" columns contains "y", then the system prints an error message on standard error.

The table uses the following notations and abbreviations:

x first argument to function
y second argument to function
fin finite value for argument
neg negative value for argument
int integral value for argument
o/f result overflowed
u/f result underflowed
|x| absolute value of x
X_TLOSS is a constant defined in <*math.h*>

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
matherr()	Thread safety	MT-Safe

EXAMPLES

The example program demonstrates the use of **matherr**() when calling *log*(3). The program takes up to three command-line arguments. The first argument is the floating-point number to be given to *log*(3). If the optional second argument is provided, then **_LIB_VERSION** is set to **_SVID_** so that **matherr**() is called, and the integer supplied in the command-line argument is used as the return value from **matherr**(). If the optional third command-line argument is supplied, then it specifies an alternative return value that **matherr**() should assign as the return value of the math function.

The following example run, where *log*(3) is given an argument of 0.0, does not use **matherr**():

```
$ ./a.out 0.0
errno: Numerical result out of range
x=-inf
```

In the following run, **matherr**() is called, and returns 0:

```
$ ./a.out 0.0 0
matherr SING exception in log() function
        args:   0.000000, 0.000000
        retval: -340282346638528859811704183484516925440.000000
log: SING error
errno: Numerical argument out of domain
x=-340282346638528859811704183484516925440.000000
```

The message "log: SING error" was printed by the C library.

In the following run, **matherr**() is called, and returns a nonzero value:

```
$ ./a.out 0.0 1
matherr SING exception in log() function
        args:   0.000000, 0.000000
        retval: -340282346638528859811704183484516925440.000000
x=-340282346638528859811704183484516925440.000000
```

In this case, the C library did not print a message, and *errno* was not set.

In the following run, **matherr**() is called, changes the return value of the math function, and returns a nonzero value:

```
$ ./a.out 0.0 1 12345.0
matherr SING exception in log() function
        args:   0.000000, 0.000000
```

```
            retval: -340282346638528859811704183484516925440.000000
    x=12345.000000
```

Program source

```

NAME

MAX, MIN − maximum or minimum of two values

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/param.h>

MAX(*a***,** *b***);**
MIN(*a***,** *b***);**

DESCRIPTION

These macros return the maximum or minimum of *a* and *b*.

RETURN VALUE

These macros return the value of one of their arguments, possibly converted to a different type (see BUGS).

ERRORS

These macros may raise the "invalid" floating-point exception when any of the arguments is NaN.

STANDARDS

GNU, BSD.

NOTES

If either of the arguments is of a floating-point type, you might prefer to use *fmax*(3) or *fmin*(3), which can handle NaN.

The arguments may be evaluated more than once, or not at all.

Some UNIX systems might provide these macros in a different header, or not at all.

BUGS

Due to the usual arithmetic conversions, the result of these macros may be very different from either of the arguments. To avoid this, ensure that both arguments have the same type.

EXAMPLES

```
#include <stdio.h>
#include <stdlib.h>
#include <sys/param.h>

int
main(int argc, char *argv[])
{
    int a, b, x;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <num> <num>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    a = atoi(argv[1]);
    b = atoi(argv[2]);
    x = MAX(a, b);
    printf("MAX(%d, %d) is %d\n", a, b, x);

    exit(EXIT_SUCCESS);
}
```

NAME

MB_CUR_MAX − maximum length of a multibyte character in the current locale

LIBRARY

Standard C library (*libc*)

SYNOPSIS

#include <stdlib.h>

DESCRIPTION

The **MB_CUR_MAX** macro defines an integer expression giving the maximum number of bytes needed to represent a single wide character in the current locale. This value is locale dependent and therefore not a compile-time constant.

RETURN VALUE

An integer in the range [1, **MB_LEN_MAX**]. The value 1 denotes traditional 8-bit encoded characters.

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

SEE ALSO

MB_LEN_MAX(3), *mblen*(3), *mbstowcs*(3), *mbtowc*(3), *wcstombs*(3), *wctomb*(3)

NAME

MB_LEN_MAX − maximum multibyte length of a character across all locales

LIBRARY

Standard C library (*libc*)

SYNOPSIS

#include <limits.h>

DESCRIPTION

The **MB_LEN_MAX** macro is the maximum number of bytes needed to represent a single wide character, in any of the supported locales.

RETURN VALUE

A constant integer greater than zero.

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

NOTES

The entities **MB_LEN_MAX** and *sizeof(wchar_t)* are totally unrelated. In glibc, **MB_LEN_MAX** is typically 16 (6 in glibc versions earlier than 2.2), while *sizeof(wchar_t)* is 4.

SEE ALSO

MB_CUR_MAX(3)

NAME

mblen − determine number of bytes in next multibyte character

LIBRARY

Standard C library (*libc*, −*lc*)

SYNOPSIS

#include <stdlib.h>

int mblen(const char *s***[.***n***], size_t** *n***);**

DESCRIPTION

If *s* is not NULL, the **mblen**() function inspects at most *n* bytes of the multibyte string starting at *s* and extracts the next complete multibyte character. It uses a static anonymous shift state known only to the **mblen**() function. If the multibyte character is not the null wide character, it returns the number of bytes that were consumed from *s*. If the multibyte character is the null wide character, it returns 0.

If the *n* bytes starting at *s* do not contain a complete multibyte character, **mblen**() returns −1. This can happen even if *n* is greater than or equal to *MB_CUR_MAX*, if the multibyte string contains redundant shift sequences.

If the multibyte string starting at *s* contains an invalid multibyte sequence before the next complete character, **mblen**() also returns −1.

If *s* is NULL, the **mblen**() function resets the shift state, known to only this function, to the initial state, and returns nonzero if the encoding has nontrivial shift state, or zero if the encoding is stateless.

RETURN VALUE

The **mblen**() function returns the number of bytes parsed from the multibyte sequence starting at *s*, if a non-null wide character was recognized. It returns 0, if a null wide character was recognized. It returns −1, if an invalid multibyte sequence was encountered or if it couldn't parse a complete multibyte character.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mblen()	Thread safety	MT-Unsafe race

VERSIONS

The function *mbrlen*(3) provides a better interface to the same functionality.

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **mblen**() depends on the **LC_CTYPE** category of the current locale.

mbrlen(3)

NAME

mbrlen − determine number of bytes in next multibyte character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <wchar.h>

size_t mbrlen(const char *s[restrict .n], size_t n,
              mbstate_t *restrict ps);
```

DESCRIPTION

The **mbrlen**() function inspects at most *n* bytes of the multibyte string starting at *s* and extracts the next complete multibyte character. It updates the shift state **ps*. If the multibyte character is not the null wide character, it returns the number of bytes that were consumed from *s*. If the multibyte character is the null wide character, it resets the shift state **ps* to the initial state and returns 0.

If the *n* bytes starting at *s* do not contain a complete multibyte character, **mbrlen**() returns *(size_t) −2*. This can happen even if *n >= MB_CUR_MAX*, if the multibyte string contains redundant shift sequences.

If the multibyte string starting at *s* contains an invalid multibyte sequence before the next complete character, **mbrlen**() returns *(size_t) −1* and sets *errno* to **EILSEQ**. In this case, the effects on **ps* are undefined.

If *ps* is NULL, a static anonymous state known only to the **mbrlen**() function is used instead.

RETURN VALUE

The **mbrlen**() function returns the number of bytes parsed from the multibyte sequence starting at *s*, if a non-null wide character was recognized. It returns 0, if a null wide character was recognized. It returns *(size_t) −1* and sets *errno* to **EILSEQ**, if an invalid multibyte sequence was encountered. It returns *(size_t) −2* if it couldn't parse a complete multibyte character, meaning that *n* should be increased.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **mbrlen**() depends on the **LC_CTYPE** category of the current locale.

SEE ALSO

mbrtowc(3)

NAME

mbrtowc − convert a multibyte sequence to a wide character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <wchar.h>

size_t mbrtowc(wchar_t *restrict pwc, const char s[restrict .n],
               size_t n, mbstate_t *restrict ps);
```

DESCRIPTION

The main case for this function is when *s* is not NULL and *pwc* is not NULL. In this case, the **mbrtowc**() function inspects at most *n* bytes of the multibyte string starting at *s*, extracts the next complete multibyte character, converts it to a wide character and stores it at **pwc*. It updates the shift state **ps*. If the converted wide character is not L'\0' (the null wide character), it returns the number of bytes that were consumed from *s*. If the converted wide character is L'\0', it resets the shift state **ps* to the initial state and returns 0.

If the *n* bytes starting at *s* do not contain a complete multibyte character, **mbrtowc**() returns *(size_t) −2*. This can happen even if *n >= MB_CUR_MAX*, if the multibyte string contains redundant shift sequences.

If the multibyte string starting at *s* contains an invalid multibyte sequence before the next complete character, **mbrtowc**() returns *(size_t) −1* and sets *errno* to **EILSEQ**. In this case, the effects on **ps* are undefined.

A different case is when *s* is not NULL but *pwc* is NULL. In this case, the **mbrtowc**() function behaves as above, except that it does not store the converted wide character in memory.

A third case is when *s* is NULL. In this case, *pwc* and *n* are ignored. If the conversion state represented by **ps* denotes an incomplete multibyte character conversion, the **mbrtowc**() function returns *(size_t) −1*, sets *errno* to **EILSEQ**, and leaves **ps* in an undefined state. Otherwise, the **mbrtowc**() function puts **ps* in the initial state and returns 0.

In all of the above cases, if *ps* is NULL, a static anonymous state known only to the **mbrtowc**() function is used instead. Otherwise, **ps* must be a valid *mbstate_t* object. An *mbstate_t* object *a* can be initialized to the initial state by zeroing it, for example using

```
memset(&a, 0, sizeof(a));
```

RETURN VALUE

The **mbrtowc**() function returns the number of bytes parsed from the multibyte sequence starting at *s*, if a non-L'\0' wide character was recognized. It returns 0, if a L'\0' wide character was recognized. It returns *(size_t) −1* and sets *errno* to **EILSEQ**, if an invalid multibyte sequence was encountered. It returns *(size_t) −2* if it couldn't parse a complete multibyte character, meaning that *n* should be increased.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

SEE ALSO

mbsinit(3), *mbsrtowcs*(3)

NAME

mbsinit − test for initial shift state

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

int mbsinit(const mbstate_t * *ps***);**

DESCRIPTION

Character conversion between the multibyte representation and the wide character representation uses conversion state, of type *mbstate_t*. Conversion of a string uses a finite-state machine; when it is interrupted after the complete conversion of a number of characters, it may need to save a state for processing the remaining characters. Such a conversion state is needed for the sake of encodings such as ISO/IEC 2022 and UTF-7.

The initial state is the state at the beginning of conversion of a string. There are two kinds of state: the one used by multibyte to wide character conversion functions, such as *mbsrtowcs*(3), and the one used by wide character to multibyte conversion functions, such as *wcsrtombs*(3), but they both fit in a *mbstate_t*, and they both have the same representation for an initial state.

For 8-bit encodings, all states are equivalent to the initial state. For multibyte encodings like UTF-8, EUC-*, BIG5, or SJIS, the wide character to multibyte conversion functions never produce non-initial states, but the multibyte to wide-character conversion functions like *mbrtowc*(3) do produce non-initial states when interrupted in the middle of a character.

One possible way to create an *mbstate_t* in initial state is to set it to zero:

```
mbstate_t state;
memset(&state, 0, sizeof(state));
```

On Linux, the following works as well, but might generate compiler warnings:

```
mbstate_t state = { 0 };
```

The function **mbsinit**() tests whether **ps* corresponds to an initial state.

RETURN VALUE

mbsinit() returns nonzero if **ps* is an initial state, or if *ps* is NULL. Otherwise, it returns 0.

ATTRIBUTES

NAME

mbsnrtowcs − convert a multibyte string to a wide-character string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <wchar.h>

size_t mbsnrtowcs(wchar_t dest[restrict .len], const char **restrict src,
                  size_t nms, size_t len, mbstate_t *restrict ps);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mbsnrtowcs():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **mbsnrtowcs**() function is like the *mbsrtowcs*(3) function, except that the number of bytes to be converted, starting at **src*, is limited to at most *nms* bytes.

If *dest* is not NULL, the **mbsnrtowcs**() function converts at most *nms* bytes from the multibyte string **src* to a wide-character string starting at *dest*. At most *len* wide characters are written to *dest*. The shift state **ps* is updated. The conversion is effectively performed by repeatedly calling *mbrtowc(dest, *src, n, ps)* where *n* is some positive number, as long as this call succeeds, and then incrementing *dest* by one and **src* by the number of bytes consumed. The conversion can stop for three reasons:

- An invalid multibyte sequence has been encountered. In this case, **src* is left pointing to the invalid multibyte sequence, *(size_t) −1* is returned, and *errno* is set to **EILSEQ**.
- The *nms* limit forces a stop, or *len* non-L'\0' wide characters have been stored at *dest*. In this case, **src* is left pointing to the next multibyte sequence to be converted, and the number of wide characters written to *dest* is returned.
- The multibyte string has been completely converted, including the terminating null wide character ('\0') (which has the side effect of bringing back **ps* to the initial state). In this case, **src* is set to NULL, and the number of wide characters written to *dest*, excluding the terminating null wide character, is returned.

According to POSIX.1, if the input buffer ends with an incomplete character, it is unspecified whether conversion stops at the end of the previous character (if any), or at the end of the input buffer. The glibc implementation adopts the former behavior.

If *dest* is NULL, *len* is ignored, and the conversion proceeds as above, except that the converted wide characters are not written out to memory, and that no destination length limit exists.

In both of the above cases, if *ps* is NULL, a static anonymous state known only to the **mbsnrtowcs**() function is used instead.

The programmer must ensure that there is room for at least *len* wide characters at *dest*.

RETURN VALUE

The **mbsnrtowcs**() function returns the number of wide characters that make up the converted part of the wide-character string, not including the terminating null wide character. If an invalid multibyte sequence was encountered, *(size_t) −1* is returned, and *errno* set to **EILSEQ**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mbsnrtowcs()	Thread safety	MT-Unsafe race:mbsnrtowcs/!ps

STANDARDS

POSIX.1-2008.

NOTES

The behavior of **mbsnrtowcs**() depends on the **LC_CTYPE** category of the current locale.

Passing NULL as *ps* is not multithread safe.

NAME

mbsrtowcs − convert a multibyte string to a wide-character string (restartable)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <wchar.h>

size_t mbsrtowcs(wchar_t dest[restrict .dsize],
                 const char **restrict src,
                 size_t dsize, mbstate_t *restrict ps);
```

DESCRIPTION

If *dest* is not NULL, convert the multibyte string **src* to a wide-character string starting at *dest*. At most *dsize* wide characters are written to *dest*. The shift state **ps* is updated. The conversion is effectively performed by repeatedly calling *mbrtowc(dest, *src, n, ps)* where *n* is some positive number, as long as this call succeeds, and then incrementing *dest* by one and **src* by the number of bytes consumed. The conversion can stop for three reasons:

- An invalid multibyte sequence has been encountered. In this case, **src* is left pointing to the invalid multibyte sequence, *(size_t) −1* is returned, and *errno* is set to **EILSEQ**.
- *dsize* non-L'\0' wide characters have been stored at *dest*. In this case, **src* is left pointing to the next multibyte sequence to be converted, and the number of wide characters written to *dest* is returned.
- The multibyte string has been completely converted, including the terminating null wide character ('\0'), which has the side effect of bringing back **ps* to the initial state. In this case, **src* is set to NULL, and the number of wide characters written to *dest*, excluding the terminating null wide character, is returned.

If *dest* is NULL, *dsize* is ignored, and the conversion proceeds as above, except that the converted wide characters are not written out to memory, and that no length limit exists.

In both of the above cases, if *ps* is NULL, a static anonymous state known only to the **mbsrtowcs**() function is used instead.

In order to avoid the case 2 above, the programmer should make sure *dsize* is greater than or equal to *mbsrtowcs(NULL,src,0,ps)+1*.

The programmer must ensure that there is room for at least *dsize* wide characters at *dest*.

This function is a restartable version of *mbstowcs*(3).

RETURN VALUE

The number of wide characters that make up the converted part of the wide-character string, not including the terminating null wide character. If an invalid multibyte sequence was encountered, *(size_t) −1* is returned, and *errno* set to **EILSEQ**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

mbstowcs − convert a multibyte string to a wide-character string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

size_t mbstowcs(wchar_t dest[restrict .dsize], const char *restrict src,
                size_t dsize);
```

DESCRIPTION

If *dest* is not NULL, convert the multibyte string *src* to a wide-character string starting at *dest*. At most *dsize* wide characters are written to *dest*. The sequence of characters in the string *src* shall begin in the initial shift state. The conversion can stop for three reasons:

- An invalid multibyte sequence has been encountered. In this case, *(size_t) −1* is returned.
- *dsize* non-L'\0' wide characters have been stored at *dest*. In this case, the number of wide characters written to *dest* is returned, but the shift state at this point is lost.
- The multibyte string has been completely converted, including the terminating null character ('\0'). In this case, the number of wide characters written to *dest*, excluding the terminating null wide character, is returned.

If *dest* is NULL, *dsize* is ignored, and the conversion proceeds as above, except that the converted wide characters are not written out to memory, and that no length limit exists.

In order to avoid the case 2 above, the programmer should make sure *dsize* is greater than or equal to *mbstowcs(NULL,src,0)+1*.

The programmer must ensure that there is room for at least *dsize* wide characters at *dest*.

RETURN VALUE

The number of wide characters that make up the converted part of the wide-character string, not including the terminating null wide character. If an invalid multibyte sequence was encountered, *(size_t) −1* is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **mbstowcs**() depends on the **LC_CTYPE** category of the current locale.

EXAMPLES

The program below illustrates the use of **mbstowcs**(), as well as some of the wide character classification functions. An example run is the following:

```
$ ./t_mbstowcs de_DE.UTF-8 Grüße!
Length of source string (excluding terminator):
    8 bytes
    6 multibyte characters

Wide character string is: Grüße! (6 characters)
    G alpha upper
    r alpha lower
    ü alpha lower
```

```
        ß alpha lower
        e alpha lower
        ! !alpha
```

Program source

```
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <wchar.h>
#include <wctype.h>

int
main(int argc, char *argv[])
{
    size_t mbslen;      /* Number of multibyte characters in source */
    wchar_t *wcs;       /* Pointer to converted wide character string */

    if (argc < 3) {
        fprintf(stderr, "Usage: %s <locale> <string>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    /* Apply the specified locale. */

    if (setlocale(LC_ALL, argv[1]) == NULL) {
        perror("setlocale");
        exit(EXIT_FAILURE);
    }

    /* Calculate the length required to hold argv[2] converted to
       a wide character string. */

    mbslen = mbstowcs(NULL, argv[2], 0);
    if (mbslen == (size_t) -1) {
        perror("mbstowcs");
        exit(EXIT_FAILURE);
    }

    /* Describe the source string to the user. */

    printf("Length of source string (excluding terminator):\n");

NAME

mbtowc − convert a multibyte sequence to a wide character

LIBRARY

Standard C library (*libc*, −*lc*)

SYNOPSIS

#include <stdlib.h>

int mbtowc(wchar_t *restrict *pwc***, const char** *s***[restrict .**n**], size_t** *n***);**

DESCRIPTION

The main case for this function is when *s* is not NULL and *pwc* is not NULL. In this case, the **mbtowc**() function inspects at most *n* bytes of the multibyte string starting at *s*, extracts the next complete multibyte character, converts it to a wide character and stores it at **pwc*. It updates an internal shift state known only to the **mbtowc**() function. If *s* does not point to a null byte ('\0'), it returns the number of bytes that were consumed from *s*, otherwise it returns 0.

If the *n* bytes starting at *s* do not contain a complete multibyte character, or if they contain an invalid multibyte sequence, **mbtowc**() returns −1. This can happen even if *n* >= *MB_CUR_MAX*, if the multibyte string contains redundant shift sequences.

A different case is when *s* is not NULL but *pwc* is NULL. In this case, the **mbtowc**() function behaves as above, except that it does not store the converted wide character in memory.

A third case is when *s* is NULL. In this case, *pwc* and *n* are ignored. The **mbtowc**() function resets the shift state, only known to this function, to the initial state, and returns nonzero if the encoding has nontrivial shift state, or zero if the encoding is stateless.

RETURN VALUE

If *s* is not NULL, the **mbtowc**() function returns the number of consumed bytes starting at *s*, or 0 if *s* points to a null byte, or −1 upon failure.

If *s* is NULL, the **mbtowc**() function returns nonzero if the encoding has nontrivial shift state, or zero if the encoding is stateless.

mcheck, mcheck_check_all, mcheck_pedantic, mprobe − heap consistency checking

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <mcheck.h>

int mcheck(void (*abortfunc)(enum mcheck_status mstatus));
int mcheck_pedantic(void (*abortfunc)(enum mcheck_status mstatus));
void mcheck_check_all(void);

enum mcheck_status mprobe(void *ptr);
```

DESCRIPTION

The **mcheck**() function installs a set of debugging hooks for the *malloc*(3) family of memory-allocation functions. These hooks cause certain consistency checks to be performed on the state of the heap. The checks can detect application errors such as freeing a block of memory more than once or corrupting the bookkeeping data structures that immediately precede a block of allocated memory.

To be effective, the **mcheck**() function must be called before the first call to *malloc*(3) or a related function. In cases where this is difficult to ensure, linking the program with *−lmcheck* inserts an implicit call to **mcheck**() (with a NULL argument) before the first call to a memory-allocation function.

The **mcheck_pedantic**() function is similar to **mcheck**(), but performs checks on all allocated blocks whenever one of the memory-allocation functions is called. This can be very slow!

The **mcheck_check_all**() function causes an immediate check on all allocated blocks. This call is effective only if **mcheck**() is called beforehand.

If the system detects an inconsistency in the heap, the caller-supplied function pointed to by *abortfunc* is invoked with a single argument, *mstatus*, that indicates what type of inconsistency was detected. If *abortfunc* is NULL, a default function prints an error message on *stderr* and calls *abort*(3).

The **mprobe**() function performs a consistency check on the block of allocated memory pointed to by *ptr*. The **mcheck**() function should be called beforehand (otherwise **mprobe**() returns **MCHECK_DISABLED**).

The following list describes the values returned by **mprobe**() or passed as the *mstatus* argument when *abortfunc* is invoked:

MCHECK_DISABLED (**mprobe**() only)
: **mcheck**() was not called before the first memory allocation function was called. Consistency checking is not possible.

MCHECK_OK (**mprobe**() only)
: No inconsistency detected.

MCHECK_HEAD
: Memory preceding an allocated block was clobbered.

MCHECK_TAIL
: Memory following an allocated block was clobbered.

MCHECK_FREE
: A block of memory was freed twice.

RETURN VALUE

mcheck() and **mcheck_pedantic**() return 0 on success, or −1 on error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mcheck(), **mcheck_pedantic**(), **mcheck_check_all**(), **mprobe**()	Thread safety	MT-Unsafe race:mcheck const:malloc_hooks

STANDARDS

GNU.

HISTORY

mcheck_pedantic()
mcheck_check_all()
: glibc 2.2.

mcheck()
mprobe()
: glibc 2.0.

NOTES

Linking a program with *−lmcheck* and using the **MALLOC_CHECK_** environment variable (described in *mallopt*(3)) cause the same kinds of errors to be detected. But, using **MALLOC_CHECK_** does not require the application to be relinked.

EXAMPLES

The program below calls **mcheck**() with a NULL argument and then frees the same block of memory twice. The following shell session demonstrates what happens when running the program:

```
$ ./a.out
About to free

About to free a second time
block freed twice
Aborted (core dumped)
```

Program source

```
#include <mcheck.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    char *p;

    if (mcheck(NULL) != 0) {
        fprintf(stderr, "mcheck() failed\n");

        exit(EXIT_FAILURE);
    }

    p = malloc(1000);

    fprintf(stderr, "About to free\n");
    free(p);
    fprintf(stderr, "\nAbout to free a second time\n");
    free(p);

    exit(EXIT_SUCCESS);
}
```

NAME

memccpy − copy memory area

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

void *memccpy(void dest[restrict .n], const void src[restrict .n],
        int c, size_t n);
```

DESCRIPTION

The **memccpy**() function copies no more than *n* bytes from memory area *src* to memory area *dest*, stopping when the character *c* is found.

If the memory areas overlap, the results are undefined.

RETURN VALUE

The **memccpy**() function returns a pointer to the next character in *dest* after *c*, or NULL if *c* was not found in the first *n* characters of *src*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

memchr, memrchr, rawmemchr − scan memory for a character

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

void *memchr(const void s[.n], int c, size_t n);
void *memrchr(const void s[.n], int c, size_t n);

[[deprecated]] void *rawmemchr(const void *s, int c);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

memrchr(), **rawmemchr**():
_GNU_SOURCE

DESCRIPTION

The **memchr**() function scans the initial *n* bytes of the memory area pointed to by *s* for the first instance of *c*. Both *c* and the bytes of the memory area pointed to by *s* are interpreted as *unsigned char*.

The **memrchr**() function is like the **memchr**() function, except that it searches backward from the end of the *n* bytes pointed to by *s* instead of forward from the beginning.

The **rawmemchr**() function is similar to **memchr**(), but it assumes (i.e., the programmer knows for certain) that an instance of *c* lies somewhere in the memory area starting at the location pointed to by *s*. If an instance of *c* is not found, the behavior is undefined. Use either *strlen*(3) or *memchr*(3) instead.

RETURN VALUE

The **memchr**() and **memrchr**() functions return a pointer to the matching byte or NULL if the character does not occur in the given memory area.

The **rawmemchr**() function returns a pointer to the matching byte.

ATTRIBUTES

NAME

memcmp − compare memory areas

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

int memcmp(const void *s1***[.***n***], const void** *s2***[.***n***], size_t** *n***);**

DESCRIPTION

The **memcmp**() function compares the first *n* bytes (each interpreted as *unsigned char*) of the memory areas *s1* and *s2*.

RETURN VALUE

The **memcmp**() function returns an integer less than, equal to, or greater than zero if the first *n* bytes of *s1* is found, respectively, to be less than, to match, or be greater than the first *n* bytes of *s2*.

For a nonzero return value, the sign is determined by the sign of the difference between the first pair of bytes (interpreted as *unsigned char*) that differ in *s1* and *s2*.

If *n* is zero, the return value is zero.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
memcmp()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD.

CAVEATS

Do not use **memcmp**() to compare confidential data, such as cryptographic secrets, because the CPU time required for the comparison depends on the contents of the addresses compared, this function is subject to timing-based side-channel attacks. In such cases, a function that performs comparisons in deterministic time, depending only on *n* (the quantity of bytes compared) is required. Some operating systems provide such a function (e.g., NetBSD's *consttime_memequal*()), but no such function is specified in POSIX. On Linux, you may need to implement such a function yourself.

NAME

memcpy − copy memory area

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

void *memcpy(void dest[restrict .n], const void src[restrict .n],
        size_t n);
```

DESCRIPTION

The **memcpy**() function copies *n* bytes from memory area *src* to memory area *dest*. The memory areas must not overlap. Use *memmove*(3) if the memory areas do overlap.

RETURN VALUE

The **memcpy**() function returns a pointer to *dest*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
memcpy()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD.

CAVEATS

Failure to observe the requirement that the memory areas do not overlap has been the source of significant bugs. (POSIX and the C standards are explicit that employing **memcpy**() with overlapping areas produces undefined behavior.) Most notably, in glibc 2.13 a performance optimization of **memcpy**() on some platforms (including x86-64) included changing the order in which bytes were copied from *src* to *dest*.

This change revealed breakages in a number of applications that performed copying with overlapping areas. Under the previous implementation, the order in which the bytes were copied had fortuitously hidden the bug, which was revealed when the copying order was reversed. In glibc 2.14, a versioned symbol was added so that old binaries (i.e., those linked against glibc versions earlier than 2.14) employed a **memcpy**() implementation that safely handles the overlapping buffers case (by providing an "older" **memcpy**() implementation that was aliased to *memmove*(3)).

NAME

memfrob − frobnicate (obfuscate) a memory area

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>

void *memfrob(void s[.n], size_t n);
```

DESCRIPTION

The **memfrob**() function obfuscates the first *n* bytes of the memory area *s* by exclusive-ORing each character with the number 42. The effect can be reversed by using **memfrob**() on the obfuscated memory area.

Note that this function is not a proper encryption routine as the XOR constant is fixed, and is suitable only for hiding strings.

RETURN VALUE

The **memfrob**() function returns a pointer to the obfuscated memory area.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
memfrob()	Thread safety	MT-Safe

STANDARDS

GNU.

SEE ALSO

bstring(3), *strfry*(3)

NAME

memmem − locate a substring

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>

void *memmem(const void haystack[.haystacklen], size_t haystacklen,
        const void needle[.needlelen], size_t needlelen);
```

DESCRIPTION

The **memmem**() function finds the start of the first occurrence of the substring *needle* of length *needlelen* in the memory area *haystack* of length *haystacklen*.

RETURN VALUE

The **memmem**() function returns a pointer to the beginning of the substring, or NULL if the substring is not found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
memmem()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

musl libc 0.9.7; FreeBSD 6.0, OpenBSD 5.4, NetBSD, Illumos.

BUGS

In glibc 2.0, if *needle* is empty, **memmem**() returns a pointer to the last byte of *haystack*. This is fixed in glibc 2.1.

SEE ALSO

bstring(3), *strstr*(3)

NAME

memmove − copy memory area

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

void *memmove(void *dest***[.***n***], const void** *src***[.***n***], size_t** *n***);**

DESCRIPTION

The **memmove**() function copies *n* bytes from memory area *src* to memory area *dest*. The memory areas may overlap: copying takes place as though the bytes in *src* are first copied into a temporary array that does not overlap *src* or *dest*, and the bytes are then copied from the temporary array to *dest*.

RETURN VALUE

The **memmove**() function returns a pointer to *dest*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

mempcpy, wmempcpy − copy memory area

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>

void *mempcpy(void dest[restrict .n], const void src[restrict .n],
        size_t n);

#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <wchar.h>

wchar_t *wmempcpy(wchar_t dest[restrict .n],
        const wchar_t src[restrict .n],
        size_t n);
```

DESCRIPTION

The **mempcpy**() function is nearly identical to the *memcpy*(3) function. It copies *n* bytes from the object beginning at *src* into the object pointed to by *dest*. But instead of returning the value of *dest* it returns a pointer to the byte following the last written byte.

This function is useful in situations where a number of objects shall be copied to consecutive memory positions.

The **wmempcpy**() function is identical but takes *wchar_t* type arguments and copies *n* wide characters.

RETURN VALUE

dest + *n*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

mkdtemp − create a unique temporary directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

char *mkdtemp(char **template*);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mkdtemp():
/* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc 2.19 and earlier: */ _BSD_SOURCE
|| /* Since glibc 2.10: */ _POSIX_C_SOURCE >= 200809L

DESCRIPTION

The **mkdtemp**() function generates a uniquely named temporary directory from *template*. The last six characters of *template* must be XXXXXX and these are replaced with a string that makes the directory name unique. The directory is then created with permissions 0700. Since it will be modified, *template* must not be a string constant, but should be declared as a character array.

RETURN VALUE

The **mkdtemp**() function returns a pointer to the modified template string on success, and NULL on failure, in which case *errno* is set to indicate the error.

ERRORS

EINVAL
The last six characters of *template* were not XXXXXX. Now *template* is unchanged.

Also see *mkdir*(2) for other possible values for *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mkdtemp()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1.91. NetBSD 1.4. POSIX.1-2008.

SEE ALSO

mktemp(1), *mkdir*(2), *mkstemp*(3), *mktemp*(3), *tempnam*(3), *tmpfile*(3), *tmpnam*(3)

NAME

mkfifo, mkfifoat − make a FIFO special file (a named pipe)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <sys/stat.h>

int mkfifo(const char *pathname, mode_t mode);

#include <fcntl.h>          /* Definition of AT_* constants */
#include <sys/stat.h>

int mkfifoat(int dirfd, const char *pathname, mode_t mode);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mkfifoat():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_ATFILE_SOURCE

DESCRIPTION

mkfifo() makes a FIFO special file with name *pathname*. *mode* specifies the FIFO's permissions. It is modified by the process's **umask** in the usual way: the permissions of the created file are **(***mode* **& ~umask)**.

A FIFO special file is similar to a pipe, except that it is created in a different way. Instead of being an anonymous communications channel, a FIFO special file is entered into the filesystem by calling **mkfifo**().

Once you have created a FIFO special file in this way, any process can open it for reading or writing, in the same way as an ordinary file. However, it has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks until some other process opens the same FIFO for writing, and vice versa. See *fifo*(7) for nonblocking handling of FIFO special files.

mkfifoat()

The **mkfifoat**() function operates in exactly the same way as **mkfifo**(), except for the differences described here.

If the pathname given in *pathname* is relative, then it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by **mkfifo**() for a relative pathname).

If *pathname* is relative and *dirfd* is the special value **AT_FDCWD**, then *pathname* is interpreted relative to the current working directory of the calling process (like *mkfifo*())

If *pathname* is absolute, then *dirfd* is ignored.

See *openat*(2) for an explanation of the need for **mkfifoat**().

RETURN VALUE

On success **mkfifo**() and **mkfifoat**() return 0. On error, −1 is returned and *errno* is set to indicate the error.

ERRORS

EACCES
One of the directories in *pathname* did not allow search (execute) permission.

EBADF
(**mkfifoat**()) *pathname* is relative but *dirfd* is neither **AT_FDCWD** nor a valid file descriptor.

EDQUOT
The user's quota of disk blocks or inodes on the filesystem has been exhausted.

EEXIST
pathname already exists. This includes the case where *pathname* is a symbolic link, dangling or not.

ENAMETOOLONG
Either the total length of *pathname* is greater than **PATH_MAX**, or an individual filename component has a length greater than **NAME_MAX**. In the GNU system, there is no imposed limit on overall filename length, but some filesystems may place limits on the length of a component.

ENOENT
A directory component in *pathname* does not exist or is a dangling symbolic link.

ENOSPC
The directory or filesystem has no room for the new file.

ENOTDIR
A component used as a directory in *pathname* is not, in fact, a directory.

ENOTDIR
(**mkfifoat**()) *pathname* is a relative pathname and *dirfd* is a file descriptor referring to a file other than a directory.

EROFS
pathname refers to a read-only filesystem.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

mkstemp, mkostemp, mkstemps, mkostemps − create a unique temporary file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int mkstemp(char *template);
int mkostemp(char *template, int  flags);
int mkstemps(char *template, int suffixlen);
int mkostemps(char *template, int suffixlen, int  flags);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mkstemp():
  _XOPEN_SOURCE >= 500
    || /* glibc >= 2.12: */ _POSIX_C_SOURCE >= 200809L
    || /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

mkostemp():
  _GNU_SOURCE

mkstemps():
  /* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

mkostemps():
  _GNU_SOURCE

DESCRIPTION

The **mkstemp**() function generates a unique temporary filename from *template*, creates and opens the file, and returns an open file descriptor for the file.

The last six characters of *template* must be "XXXXXX" and these are replaced with a string that makes the filename unique. Since it will be modified, *template* must not be a string constant, but should be declared as a character array.

The file is created with permissions 0600, that is, read plus write for owner only. The returned file descriptor provides both read and write access to the file. The file is opened with the *open*(2) **O_EXCL** flag, guaranteeing that the caller is the process that creates the file.

The **mkostemp**() function is like **mkstemp**(), with the difference that the following bits—with the same meaning as for *open*(2)—may be specified in *flags*: **O_APPEND**, **O_CLOEXEC**, and **O_SYNC**. Note that when creating the file, **mkostemp**() includes the values **O_RDWR**, **O_CREAT**, and **O_EXCL** in the *flags* argument given to *open*(2); including these values in the *flags* argument given to **mkostemp**() is unnecessary, and produces errors on some systems.

The **mkstemps**() function is like **mkstemp**(), except that the string in *template* contains a suffix of *suffixlen* characters. Thus, *template* is of the form *prefixXXXXXXsuffix*, and the string XXXXXX is modified as for **mkstemp**().

The **mkostemps**() function is to **mkstemps**() as **mkostemp**() is to **mkstemp**().

RETURN VALUE

On success, these functions return the file descriptor of the temporary file. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EEXIST
: Could not create a unique temporary filename. Now the contents of *template* are undefined.

EINVAL
: For **mkstemp**() and **mkostemp**(): The last six characters of *template* were not XXXXXX; now *template* is unchanged.

  For **mkstemps**() and **mkostemps**(): *template* is less than *(6 + suffixlen)* characters long, or the last 6 characters before the suffix in *template* were not XXXXXX.

These functions may also fail with any of the errors described for *open*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mkstemp(), **mkostemp**(), **mkstemps**(), **mkostemps**()	Thread safety	MT-Safe

STANDARDS

mkstemp()
: POSIX.1-2001.

mkstemps()
: BSD.

mkostemp()
mkostemps()
: GNU.

HISTORY

mkstemp()
: 4.3BSD, POSIX.1-2001.

mkstemps()
: glibc 2.11. BSD, Mac OS X, Solaris, Tru64.

mkostemp()
: glibc 2.7.

mkostemps()
: glibc 2.11.

In glibc versions 2.06 and earlier, the file is created with permissions 0666, that is, read and write for all users. This old behavior may be a security risk, especially since other UNIX flavors use 0600, and somebody might overlook this detail when porting programs. POSIX.1-2008 adds a requirement that the file be created with mode 0600.

More generally, the POSIX specification of **mkstemp**() does not say anything about file modes, so the application should make sure its file mode creation mask (see *umask*(2)) is set appropriately before calling **mkstemp**() (and *mkostemp*())

NAME

mktemp − make a unique temporary filename

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

char *mktemp(char **template*);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mktemp():
Since glibc 2.12:
(_XOPEN_SOURCE >= 500) && ! (_POSIX_C_SOURCE >= 200112L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE
Before glibc 2.12:
_BSD_SOURCE || _SVID_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

Never use this function; see BUGS.

The **mktemp**() function generates a unique temporary filename from *template*. The last six characters of *template* must be XXXXXX and these are replaced with a string that makes the filename unique. Since it will be modified, *template* must not be a string constant, but should be declared as a character array.

RETURN VALUE

The **mktemp**() function always returns *template*. If a unique name was created, the last six bytes of *template* will have been modified in such a way that the resulting name is unique (i.e., does not exist already) If a unique name could not be created, *template* is made an empty string, and *errno* is set to indicate the error.

ERRORS

EINVAL
The last six characters of *template* were not XXXXXX.

ATTRIBUTES

HISTORY

4.3BSD, POSIX.1-2001. Removed in POSIX.1-2008.

BUGS

Never use **mktemp**(). Some implementations follow 4.3BSD and replace XXXXXX by the current process ID and a single letter, so that at most 26 different names can be returned. Since on the one hand the names are easy to guess, and on the other hand there is a race between testing whether the name exists and opening the file, every use of **mktemp**() is a security risk. The race is avoided by *mkstemp*(3) and *mkdtemp*(3).

NAME

modf, modff, modfl − extract signed integral and fractional values from floating-point number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double modf(double x, double *iptr);
float modff(float x, float *iptr);
long double modfl(long double x, long double *iptr);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

modff(), **modfl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions break the argument *x* into an integral part and a fractional part, each of which has the same sign as *x*. The integral part is stored in the location pointed to by *iptr*.

RETURN VALUE

These functions return the fractional part of *x*.

If *x* is a NaN, a NaN is returned, and **iptr* is set to a NaN.

If *x* is positive infinity (negative infinity), +0 (−0) is returned, and **iptr* is set to positive infinity (negative infinity).

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

mpool − shared memory buffer pool

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <db.h>
#include <mpool.h>

MPOOL *mpool_open(DBT *_key_, int _fd_, pgno_t _pagesize_, pgno_t _maxcache_);

void mpool_filter(MPOOL *_mp_, void (*pgin)(void *, pgno_t, void *),
void (*_pgout_)(void *, pgno_t, void *),
void *_pgcookie_);

void *mpool_new(MPOOL *_mp_, pgno_t *_pgnoaddr_);
void *mpool_get(MPOOL *_mp_, pgno_t _pgno_, unsigned int _flags_);
int mpool_put(MPOOL *_mp_, void *_pgaddr_, unsigned int _flags_);

int mpool_sync(MPOOL *_mp_);
int mpool_close(MPOOL *_mp_);

DESCRIPTION

Note well: This page documents interfaces provided up until glibc 2.1. Since glibc 2.2, glibc no longer provides these interfaces. Probably, you are looking for the APIs provided by the *libdb* library instead.

Mpool is the library interface intended to provide page oriented buffer management of files. The buffers may be shared between processes.

The function **mpool_open**() initializes a memory pool. The *key* argument is the byte string used to negotiate between multiple processes wishing to share buffers. If the file buffers are mapped in shared memory, all processes using the same key will share the buffers. If *key* is NULL, the buffers are mapped into private memory. The *fd* argument is a file descriptor for the underlying file, which must be seekable. If *key* is non-NULL and matches a file already being mapped, the *fd* argument is ignored.

The *pagesize* argument is the size, in bytes, of the pages into which the file is broken up. The *maxcache* argument is the maximum number of pages from the underlying file to cache at any one time. This value is not relative to the number of processes which share a file's buffers, but will be the largest value specified by any of the processes sharing the file.

The **mpool_filter**() function is intended to make transparent input and output processing of the pages possible. If the *pgin* function is specified, it is called each time a buffer is read into the memory pool from the backing file. If the *pgout* function is specified, it is called each time a buffer is written into the backing file. Both functions are called with the *pgcookie* pointer, the page number and a pointer to the page to being read or written.

The function **mpool_new**() takes an *MPOOL* pointer and an address as arguments. If a new page can be allocated, a pointer to the page is returned and the page number is stored into the *pgnoaddr* address. Otherwise, NULL is returned and *errno* is set.

The function **mpool_get**() takes an *MPOOL* pointer and a page number as arguments. If the page exists, a pointer to the page is returned. Otherwise, NULL is returned and *errno* is set. The *flags* argument is not currently used.

The function **mpool_put**() unpins the page referenced by *pgaddr*. *pgaddr* must be an address previously returned by **mpool_get**() or **mpool_new**(). The flag value is specified by ORing any of the following values:

MPOOL_DIRTY
The page has been modified and needs to be written to the backing file.

mpool_put() returns 0 on success and −1 if an error occurs.

The function **mpool_sync**() writes all modified pages associated with the *MPOOL* pointer to the backing file. **mpool_sync**() returns 0 on success and −1 if an error occurs.

The **mpool_close**() function free's up any allocated memory associated with the memory pool cookie. Modified pages are **not** written to the backing file. **mpool_close**() returns 0 on success and −1 if an

error occurs.

ERRORS

The **mpool_open**() function may fail and set *errno* for any of the errors specified for the library routine *malloc*(3).

The **mpool_get**() function may fail and set *errno* for the following:

EINVAL The requested record doesn't exist.

The **mpool_new**() and **mpool_get**() functions may fail and set *errno* for any of the errors specified for the library routines *read*(2), *write*(2), and *malloc*(3).

The **mpool_sync**() function may fail and set *errno* for any of the errors specified for the library routine *write*(2).

The **mpool_close**() function may fail and set *errno* for any of the errors specified for the library routine *free*(3).

NAME

mq_close − close a message queue descriptor

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <mqueue.h>

int mq_close(mqd_t *mqdes***);**

DESCRIPTION

mq_close() closes the message queue descriptor *mqdes*.

If the calling process has attached a notification request (see *mq_notify*(3)) to this message queue via *mqdes*, then this request is removed, and another process can now attach a notification request.

RETURN VALUE

On success **mq_close**() returns 0; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EBADF

The message queue descriptor specified in *mqdes* is invalid.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mq_close()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

All open message queues are automatically closed on process termination, or upon *execve*(2).

SEE ALSO

mq_getattr(3), *mq_notify*(3), *mq_open*(3), *mq_receive*(3), *mq_send*(3), *mq_unlink*(3), *mq_overview*(7)

NAME

mq_getattr, mq_setattr − get/set message queue attributes

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <mqueue.h>

int mq_getattr(mqd_t mqdes, struct mq_attr *attr);
int mq_setattr(mqd_t mqdes, const struct mq_attr *restrict newattr,
        struct mq_attr *restrict oldattr);
```

DESCRIPTION

mq_getattr() and **mq_setattr**() respectively retrieve and modify attributes of the message queue referred to by the message queue descriptor *mqdes*.

mq_getattr() returns an *mq_attr* structure in the buffer pointed by *attr*. This structure is defined as:

```
struct mq_attr {
    long mq_flags;       /* Flags: 0 or O_NONBLOCK */
    long mq_maxmsg;      /* Max. # of messages on queue */
    long mq_msgsize;     /* Max. message size (bytes) */
    long mq_curmsgs;     /* # of messages currently in queue */
};
```

The *mq_flags* field contains flags associated with the open message queue description. This field is initialized when the queue is created by *mq_open*(3). The only flag that can appear in this field is **O_NONBLOCK**.

The *mq_maxmsg* and *mq_msgsize* fields are set when the message queue is created by *mq_open*(3). The *mq_maxmsg* field is an upper limit on the number of messages that may be placed on the queue using *mq_send*(3). The *mq_msgsize* field is an upper limit on the size of messages that may be placed on the queue. Both of these fields must have a value greater than zero. Two */proc* files that place ceilings on the values for these fields are described in *mq_overview*(7).

The *mq_curmsgs* field returns the number of messages currently held in the queue.

mq_setattr() sets message queue attributes using information supplied in the *mq_attr* structure pointed to by *newattr*. The only attribute that can be modified is the setting of the **O_NONBLOCK** flag in *mq_flags*. The other fields in *newattr* are ignored. If the *oldattr* field is not NULL, then the buffer that it points to is used to return an *mq_attr* structure that contains the same information that is returned by **mq_getattr**().

RETURN VALUE

On success **mq_getattr**() and **mq_setattr**() return 0; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EBADF
: The message queue descriptor specified in *mqdes* is invalid.

EINVAL
: *newattr−>mq_flags* contained set bits other than **O_NONBLOCK**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mq_getattr(), **mq_setattr**()	Thread safety	MT-Safe

VERSIONS

On Linux, **mq_getattr**() and **mq_setattr**() are library functions layered on top of the *mq_getsetattr*(2) system call.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

The program below can be used to show the default *mq_maxmsg* and *mq_msgsize* values that are assigned to a message queue that is created with a call to *mq_open*(3) in which the *attr* argument is NULL. Here is an example run of the program:

```
$ ./a.out /testq
Maximum # of messages on queue:   10
Maximum message size:             8192
```

Since Linux 3.5, the following */proc* files (described in *mq_overview*(7)) can be used to control the defaults:

```
$ uname -sr
Linux 3.8.0
$ cat /proc/sys/fs/mqueue/msg_default
10
$ cat /proc/sys/fs/mqueue/msgsize_default
8192
```

Program source

```
#include <fcntl.h>
#include <mqueue.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/stat.h>
#include <unistd.h>

#define errExit(msg)    do { perror(msg); exit(EXIT_FAILURE); \
                        } while (0)

int
main(int argc, char *argv[])
{
    mqd_t mqd;
    struct mq_attr attr;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s mq-name\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    mqd = mq_open(argv[1], O_CREAT | O_EXCL, 0600, NULL);
    if (mqd == (mqd_t) -1)
        errExit("mq_open");

    if (mq_getattr(mqd, &attr) == -1)
        errExit("mq_getattr");

    printf("Maximum # of messages on queue:   %ld\n", attr.mq_maxmsg);
    printf("Maximum message size:             %ld\n", attr.mq_msgsize);

    if (mq_unlink(argv[1]) == -1)
        errExit("mq_unlink");

    exit(EXIT_SUCCESS);
}
```

NAME

mq_notify − register for notification when a message is available

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <mqueue.h>
#include <signal.h>          /* Definition of SIGEV_* constants */

int mq_notify(mqd_t mqdes, const struct sigevent *sevp);
```

DESCRIPTION

mq_notify() allows the calling process to register or unregister for delivery of an asynchronous notification when a new message arrives on the empty message queue referred to by the message queue descriptor *mqdes*.

The *sevp* argument is a pointer to a *sigevent* structure. For the definition and general details of this structure, see *sigevent*(3type).

If *sevp* is a non-null pointer, then **mq_notify**() registers the calling process to receive message notification. The *sigev_notify* field of the *sigevent* structure to which *sevp* points specifies how notification is to be performed. This field has one of the following values:

SIGEV_NONE
: A "null" notification: the calling process is registered as the target for notification, but when a message arrives, no notification is sent.

SIGEV_SIGNAL
: Notify the process by sending the signal specified in *sigev_signo*. See *sigevent*(3type) for general details. The *si_code* field of the *siginfo_t* structure will be set to **SI_MESGQ**. In addition, *si_pid* will be set to the PID of the process that sent the message, and *si_uid* will be set to the real user ID of the sending process.

SIGEV_THREAD
: Upon message delivery, invoke *sigev_notify_function* as if it were the start function of a new thread. See *sigevent*(3type) for details.

Only one process can be registered to receive notification from a message queue.

If *sevp* is NULL, and the calling process is currently registered to receive notifications for this message queue, then the registration is removed; another process can then register to receive a message notification for this queue.

Message notification occurs only when a new message arrives and the queue was previously empty. If the queue was not empty at the time **mq_notify**() was called, then a notification will occur only after the queue is emptied and a new message arrives.

If another process or thread is waiting to read a message from an empty queue using *mq_receive*(3), then any message notification registration is ignored: the message is delivered to the process or thread calling *mq_receive*(3), and the message notification registration remains in effect.

Notification occurs once: after a notification is delivered, the notification registration is removed, and another process can register for message notification. If the notified process wishes to receive the next notification, it can use **mq_notify**() to request a further notification. This should be done before emptying all unread messages from the queue. (Placing the queue in nonblocking mode is useful for emptying the queue of messages without blocking once it is empty.)

RETURN VALUE

On success **mq_notify**() returns 0; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EBADF
: The message queue descriptor specified in *mqdes* is invalid.

EBUSY
: Another process has already registered to receive notification for this message queue.

EINVAL
sevp->sigev_notify is not one of the permitted values; or *sevp->sigev_notify* is **SIGEV_SIGNAL** and *sevp->sigev_signo* is not a valid signal number.

ENOMEM
Insufficient memory.

POSIX.1-2008 says that an implementation *may* generate an **EINVAL** error if *sevp* is NULL, and the caller is not currently registered to receive notifications for the queue *mqdes*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mq_notify()	Thread safety	MT-Safe

VERSIONS

C library/kernel differences

In the glibc implementation, the **mq_notify**() library function is implemented on top of the system call of the same name. When *sevp* is NULL, or specifies a notification mechanism other than **SIGEV_THREAD**, the library function directly invokes the system call. For **SIGEV_THREAD**, much of the implementation resides within the library, rather than the kernel. (This is necessarily so, since the thread involved in handling the notification is one that must be managed by the C library POSIX threads implementation.) The implementation involves the use of a raw *netlink*(7) socket and creates a new thread for each notification that is delivered to the process.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

The following program registers a notification request for the message queue named in its command-line argument. Notification is performed by creating a thread. The thread executes a function which reads one message from the queue and then terminates the process.

Program source

```
#include <mqueue.h>
#include <pthread.h>
#include <signal.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

#define handle_error(msg) \
    do { perror(msg); exit(EXIT_FAILURE); } while (0)

static void                     /* Thread start function */
tfunc(union sigval sv)
{
    struct mq_attr attr;
    ssize_t nr;
    void *buf;
    mqd_t mqdes = *((mqd_t *) sv.sival_ptr);

    /* Determine max. msg size; allocate buffer to receive msg */

    if (mq_getattr(mqdes, &attr) == -1)
        handle_error("mq_getattr");
    buf = malloc(attr.mq_msgsize);
    if (buf == NULL)
        handle_error("malloc");
```

```
        nr = mq_receive(mqdes, buf, attr.mq_msgsize, NULL);
        if (nr == -1)
            handle_error("mq_receive");

        printf("Read %zd bytes from MQ\n", nr);
        free(buf);
        exit(EXIT_SUCCESS);         /* Terminate the process */
    }

    int
    main(int argc, char *argv[])
    {
        mqd_t mqdes;
        struct sigevent sev;

        if (argc != 2) {
            fprintf(stderr, "Usage: %s <mq-name>\n", argv[0]);
            exit(EXIT_FAILURE);
        }

        mqdes = mq_open(argv[1], O_RDONLY);
        if (mqdes == (mqd_t) -1)
            handle_error("mq_open");

        sev.sigev_notify = SIGEV_THREAD;
        sev.sigev_notify_function = tfunc;
        sev.sigev_notify_attributes = NULL;
        sev.sigev_value.sival_ptr = &mqdes;   /* Arg. to thread func. */
        if (mq_notify(mqdes, &sev) == -1)
            handle_error("mq_notify");

        pause();    /* Process will be terminated by thread function */
    }
```

SEE ALSO

mq_close(3), *mq_getattr*(3), *mq_open*(3), *mq_receive*(3), *mq_send*(3), *mq_unlink*(3), *mq_overview*(7), *sigevent*(3type)

NAME

mq_open − open a message queue

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <fcntl.h>          /* For O_* constants */
#include <sys/stat.h>       /* For mode constants */
#include <mqueue.h>

mqd_t mq_open(const char *name, int oflag);
mqd_t mq_open(const char *name, int oflag, mode_t mode,
              struct mq_attr *attr);
```

DESCRIPTION

mq_open() creates a new POSIX message queue or opens an existing queue. The queue is identified by *name*. For details of the construction of *name*, see *mq_overview*(7).

The *oflag* argument specifies flags that control the operation of the call. (Definitions of the flags values can be obtained by including <*fcntl.h*>.) Exactly one of the following must be specified in *oflag*:

O_RDONLY
: Open the queue to receive messages only.

O_WRONLY
: Open the queue to send messages only.

O_RDWR
: Open the queue to both send and receive messages.

Zero or more of the following flags can additionally be *OR*ed in *oflag*:

O_CLOEXEC (since Linux 2.6.26)
: Set the close-on-exec flag for the message queue descriptor. See *open*(2) for a discussion of why this flag is useful.

O_CREAT
: Create the message queue if it does not exist. The owner (user ID) of the message queue is set to the effective user ID of the calling process. The group ownership (group ID) is set to the effective group ID of the calling process.

O_EXCL
: If **O_CREAT** was specified in *oflag*, and a queue with the given *name* already exists, then fail with the error **EEXIST**.

O_NONBLOCK
: Open the queue in nonblocking mode. In circumstances where *mq_receive*(3) and *mq_send*(3) would normally block, these functions instead fail with the error **EAGAIN**.

If **O_CREAT** is specified in *oflag*, then two additional arguments must be supplied. The *mode* argument specifies the permissions to be placed on the new queue, as for *open*(2). (Symbolic definitions for the permissions bits can be obtained by including <*sys/stat.h*>.) The permissions settings are masked against the process umask.

The fields of the *struct mq_attr* pointed to *attr* specify the maximum number of messages and the maximum size of messages that the queue will allow. This structure is defined as follows:

```
struct mq_attr {
    long mq_flags;       /* Flags (ignored for mq_open()) */
    long mq_maxmsg;      /* Max. # of messages on queue */
    long mq_msgsize;     /* Max. message size (bytes) */
    long mq_curmsgs;     /* # of messages currently in queue
                            (ignored for mq_open()) */
};
```

Only the *mq_maxmsg* and *mq_msgsize* fields are employed when calling **mq_open**(); the values in the remaining fields are ignored.

If *attr* is NULL, then the queue is created with implementation-defined default attributes. Since Linux 3.5, two */proc* files can be used to control these defaults; see *mq_overview*(7) for details.

RETURN VALUE

On success, **mq_open**() returns a message queue descriptor for use by other message queue functions. On error, **mq_open**() returns *(mqd_t) −1*, with *errno* set to indicate the error.

ERRORS

EACCES
The queue exists, but the caller does not have permission to open it in the specified mode.

EACCES
name contained more than one slash.

EEXIST
Both **O_CREAT** and **O_EXCL** were specified in *oflag*, but a queue with this *name* already exists.

EINVAL
name doesn't follow the format in *mq_overview*(7).

EINVAL
O_CREAT was specified in *oflag*, and *attr* was not NULL, but *attr−>mq_maxmsg* or *attr−>mq_msqsize* was invalid. Both of these fields must be greater than zero. In a process that is unprivileged (does not have the **CAP_SYS_RESOURCE** capability), *attr−>mq_maxmsg* must be less than or equal to the *msg_max* limit, and *attr−>mq_msgsize* must be less than or equal to the *msgsize_max* limit. In addition, even in a privileged process, *attr−>mq_maxmsg* cannot exceed the **HARD_MAX** limit. (See *mq_overview*(7) for details of these limits.)

EMFILE
The per-process limit on the number of open file and message queue descriptors has been reached (see the description of **RLIMIT_NOFILE** in *getrlimit*(2)).

ENAMETOOLONG
name was too long.

ENFILE
The system-wide limit on the total number of open files and message queues has been reached.

ENOENT
The **O_CREAT** flag was not specified in *oflag*, and no queue with this *name* exists.

ENOENT
name was just "/" followed by no other characters.

ENOMEM
Insufficient memory.

ENOSPC
Insufficient space for the creation of a new message queue. This probably occurred because the *queues_max* limit was encountered; see *mq_overview*(7).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mq_open()	Thread safety	MT-Safe

VERSIONS

C library/kernel differences

The **mq_open**() library function is implemented on top of a system call of the same name. The library function performs the check that the *name* starts with a slash (/), giving the **EINVAL** error if it does not. The kernel system call expects *name* to contain no preceding slash, so the C library function passes *name* without the preceding slash (i.e., *name+1*) to the system call.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

BUGS

Before Linux 2.6.14, the process umask was not applied to the permissions specified in *mode*.

NAME

mq_receive, mq_timedreceive − receive a message from a message queue

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <mqueue.h>

ssize_t mq_receive(mqd_t mqdes, char msg_ptr[.msg_len],
                   size_t msg_len, unsigned int *msg_prio);

#include <time.h>
#include <mqueue.h>

ssize_t mq_timedreceive(mqd_t mqdes, char *restrict msg_ptr[.msg_len],
                        size_t msg_len, unsigned int *restrict msg_prio,
                        const struct timespec *restrict abs_timeout);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mq_timedreceive():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

mq_receive() removes the oldest message with the highest priority from the message queue referred to by the message queue descriptor *mqdes*, and places it in the buffer pointed to by *msg_ptr*. The *msg_len* argument specifies the size of the buffer pointed to by *msg_ptr*; this must be greater than or equal to the *mq_msgsize* attribute of the queue (see *mq_getattr*(3)). If *msg_prio* is not NULL, then the buffer to which it points is used to return the priority associated with the received message.

If the queue is empty, then, by default, **mq_receive**() blocks until a message becomes available, or the call is interrupted by a signal handler. If the **O_NONBLOCK** flag is enabled for the message queue description, then the call instead fails immediately with the error **EAGAIN**.

mq_timedreceive() behaves just like **mq_receive**(), except that if the queue is empty and the **O_NONBLOCK** flag is not enabled for the message queue description, then *abs_timeout* points to a structure which specifies how long the call will block. This value is an absolute timeout in seconds and nanoseconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC), specified in a *timespec*(3) structure.

If no message is available, and the timeout has already expired by the time of the call, **mq_timedreceive**() returns immediately.

RETURN VALUE

On success, **mq_receive**() and **mq_timedreceive**() return the number of bytes in the received message; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EAGAIN
: The queue was empty, and the **O_NONBLOCK** flag was set for the message queue description referred to by *mqdes*.

EBADF
: The descriptor specified in *mqdes* was invalid or not opened for reading.

EINTR
: The call was interrupted by a signal handler; see *signal*(7).

EINVAL
: The call would have blocked, and *abs_timeout* was invalid, either because *tv_sec* was less than zero, or because *tv_nsec* was less than zero or greater than 1000 million.

EMSGSIZE
: *msg_len* was less than the *mq_msgsize* attribute of the message queue.

ETIMEDOUT
: The call timed out before a message could be transferred.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mq_receive(), **mq_timedreceive**()	Thread safety	MT-Safe

VERSIONS

On Linux, **mq_timedreceive**() is a system call, and **mq_receive**() is a library function layered on top of that system call.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NAME

mq_send, mq_timedsend − send a message to a message queue

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <mqueue.h>

int mq_send(mqd_t mqdes, const char msg_ptr[.msg_len],
            size_t msg_len, unsigned int msg_prio);

#include <time.h>
#include <mqueue.h>

int mq_timedsend(mqd_t mqdes, const char msg_ptr[.msg_len],
            size_t msg_len, unsigned int msg_prio,
            const struct timespec *abs_timeout);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

mq_timedsend():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

mq_send() adds the message pointed to by *msg_ptr* to the message queue referred to by the message queue descriptor *mqdes*. The *msg_len* argument specifies the length of the message pointed to by *msg_ptr*; this length must be less than or equal to the queue's *mq_msgsize* attribute. Zero-length messages are allowed.

The *msg_prio* argument is a nonnegative integer that specifies the priority of this message. Messages are placed on the queue in decreasing order of priority, with newer messages of the same priority being placed after older messages with the same priority. See *mq_overview*(7) for details on the range for the message priority.

If the message queue is already full (i.e., the number of messages on the queue equals the queue's *mq_maxmsg* attribute), then, by default, **mq_send**() blocks until sufficient space becomes available to allow the message to be queued, or until the call is interrupted by a signal handler. If the **O_NONBLOCK** flag is enabled for the message queue description, then the call instead fails immediately with the error **EAGAIN**.

mq_timedsend() behaves just like **mq_send**(), except that if the queue is full and the **O_NONBLOCK** flag is not enabled for the message queue description, then *abs_timeout* points to a structure which specifies how long the call will block. This value is an absolute timeout in seconds and nanoseconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC), specified in a *timespec*(3) structure.

If the message queue is full, and the timeout has already expired by the time of the call, **mq_timedsend**() returns immediately.

RETURN VALUE

On success, **mq_send**() and **mq_timedsend**() return zero; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EAGAIN
: The queue was full, and the **O_NONBLOCK** flag was set for the message queue description referred to by *mqdes*.

EBADF
: The descriptor specified in *mqdes* was invalid or not opened for writing.

EINTR
: The call was interrupted by a signal handler; see *signal*(7).

EINVAL
: The call would have blocked, and *abs_timeout* was invalid, either because *tv_sec* was less than zero, or because *tv_nsec* was less than zero or greater than 1000 million.

EMSGSIZE
msg_len was greater than the *mq_msgsize* attribute of the message queue.

ETIMEDOUT
The call timed out before a message could be transferred.

NAME

mq_unlink − remove a message queue

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

#include <mqueue.h>

int mq_unlink(const char *****name*);**

DESCRIPTION

mq_unlink() removes the specified message queue *name*. The message queue name is removed immediately. The queue itself is destroyed once any other processes that have the queue open close their descriptors referring to the queue.

RETURN VALUE

On success **mq_unlink**() returns 0; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EACCES

The caller does not have permission to unlink this message queue.

ENAMETOOLONG

name was too long.

ENOENT

There is no message queue with the given *name*.

NAME

mtrace, muntrace − malloc tracing

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <mcheck.h>

void mtrace(void);
void muntrace(void);

DESCRIPTION

The **mtrace**() function installs hook functions for the memory-allocation functions (**malloc**(3), *realloc*(3) *memalign*(3), *free*(3)). These hook functions record tracing information about memory allocation and deallocation. The tracing information can be used to discover memory leaks and attempts to free nonallocated memory in a program.

The **muntrace**() function disables the hook functions installed by **mtrace**(), so that tracing information is no longer recorded for the memory-allocation functions. If no hook functions were successfully installed by **mtrace**(), **muntrace**() does nothing.

When **mtrace**() is called, it checks the value of the environment variable **MALLOC_TRACE**, which should contain the pathname of a file in which the tracing information is to be recorded. If the pathname is successfully opened, it is truncated to zero length.

If **MALLOC_TRACE** is not set, or the pathname it specifies is invalid or not writable, then no hook functions are installed, and **mtrace**() has no effect. In set-user-ID and set-group-ID programs, **MALLOC_TRACE** is ignored, and **mtrace**() has no effect.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
mtrace(), **muntrace**()	Thread safety	MT-Unsafe

STANDARDS

GNU.

NOTES

In normal usage, **mtrace**() is called once at the start of execution of a program, and **muntrace**() is never called.

The tracing output produced after a call to **mtrace**() is textual, but not designed to be human readable. The GNU C library provides a Perl script, *mtrace*(1), that interprets the trace log and produces human-readable output. For best results, the traced program should be compiled with debugging enabled, so that line-number information is recorded in the executable.

The tracing performed by **mtrace**() incurs a performance penalty (if **MALLOC_TRACE** points to a valid, writable pathname).

BUGS

The line-number information produced by *mtrace*(1) is not always precise: the line number references may refer to the previous or following (nonblank) line of the source code.

EXAMPLES

The shell session below demonstrates the use of the **mtrace**() function and the *mtrace*(1) command in a program that has memory leaks at two different locations. The demonstration uses the following program:

$ **cat t_mtrace.c**

```
#include <mcheck.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
```

```
    mtrace();

    for (unsigned int j = 0; j < 2; j++)
        malloc(100);            /* Never freed--a memory leak */

    calloc(16, 16);             /* Never freed--a memory leak */
    exit(EXIT_SUCCESS);
}
```

When we run the program as follows, we see that **mtrace**() diagnosed memory leaks at two different locations in the program:

```
$ cc -g t_mtrace.c -o t_mtrace
$ export MALLOC_TRACE=/tmp/t
$ ./t_mtrace
$ mtrace ./t_mtrace $MALLOC_TRACE
Memory not freed:
-----------------
   Address     Size     Caller
0x084c9378     0x64  at /home/cecilia/t_mtrace.c:12
0x084c93e0     0x64  at /home/cecilia/t_mtrace.c:12
0x084c9448    0x100  at /home/cecilia/t_mtrace.c:16
```

The first two messages about unfreed memory correspond to the two *malloc*(3) calls inside the *for* loop. The final message corresponds to the call to *calloc*(3) (which in turn calls *malloc*(3)).

NAME

nan, nanf, nanl − return 'Not a Number'

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <math.h>

double nan(const char ****tagp*);**
float nanf(const char ****tagp*);**
long double nanl(const char ****tagp*);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

nan(), **nanf**(), **nanl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions return a representation (determined by *tagp*) of a quiet NaN. If the implementation does not support quiet NaNs, these functions return zero.

The call *nan("char−sequence")* is equivalent to:

```
strtod("NAN(char-sequence)", NULL);
```

Similarly, calls to **nanf**() and **nanl**() are equivalent to analogous calls to *strtof*(3) and *strtold*(3).

The argument *tagp* is used in an unspecified manner. On IEEE 754 systems, there are many representations of NaN, and *tagp* selects one. On other systems it may do nothing.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
nan(), **nanf**(), **nanl**()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

NAME

netlink − Netlink macros

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <asm/types.h>
#include <linux/netlink.h>

int NLMSG_ALIGN(size_t *len***);**
int NLMSG_LENGTH(size_t *len***);**
int NLMSG_SPACE(size_t *len***);**
void *NLMSG_DATA(struct nlmsghdr *****nlh*);**
struct nlmsghdr *NLMSG_NEXT(struct nlmsghdr *****nlh*, **int** *len***);**
int NLMSG_OK(struct nlmsghdr *****nlh*, **int** *len***);**
int NLMSG_PAYLOAD(struct nlmsghdr *****nlh*, **int** *len***);**

DESCRIPTION

<*linux/netlink.h*> defines several standard macros to access or create a netlink datagram. They are similar in spirit to the macros defined in *cmsg*(3) for auxiliary data. The buffer passed to and from a netlink socket should be accessed using only these macros.

NLMSG_ALIGN()
: Round the length of a netlink message up to align it properly.

NLMSG_LENGTH()
: Given the payload length, *len*, this macro returns the aligned length to store in the *nlmsg_len* field of the *nlmsghdr*.

NLMSG_SPACE()
: Return the number of bytes that a netlink message with payload of *len* would occupy.

NLMSG_DATA()
: Return a pointer to the payload associated with the passed *nlmsghdr*.

NLMSG_NEXT()
: Get the next *nlmsghdr* in a multipart message. The caller must check if the current *nlmsghdr* didn't have the **NLMSG_DONE** set—this function doesn't return NULL on end. The *len* argument is an lvalue containing the remaining length of the message buffer. This macro decrements it by the length of the message header.

NLMSG_OK()
: Return true if the netlink message is not truncated and is in a form suitable for parsing.

NLMSG_PAYLOAD()
: Return the length of the payload associated with the *nlmsghdr*.

VERSIONS

It is often better to use netlink via *libnetlink* than via the low-level kernel interface.

STANDARDS

Linux.

libnetlink(3), *netlink*(7)

NAME

newlocale, freelocale − create, modify, and free a locale object

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <locale.h>

locale_t newlocale(int category_mask, const char *locale,
                   locale_t base);
void freelocale(locale_t locobj);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

newlocale(), **freelocale**():
Since glibc 2.10:
_XOPEN_SOURCE >= 700
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **newlocale**() function creates a new locale object, or modifies an existing object, returning a reference to the new or modified object as the function result. Whether the call creates a new object or modifies an existing object is determined by the value of *base*:

- If *base* is *(locale_t) 0*, a new object is created.
- If *base* refers to valid existing locale object (i.e., an object returned by a previous call to **newlocale**() or *duplocale*(3)), then that object is modified by the call. If the call is successful, the contents of *base* are unspecified (in particular, the object referred to by *base* may be freed, and a new object created). Therefore, the caller should ensure that it stops using *base* before the call to **newlocale**(), and should subsequently refer to the modified object via the reference returned as the function result. If the call fails, the contents of *base* remain valid and unchanged.

If *base* is the special locale object **LC_GLOBAL_LOCALE** (see *duplocale*(3)), or is not *(locale_t) 0* and is not a valid locale object handle, the behavior is undefined.

The *category_mask* argument is a bit mask that specifies the locale categories that are to be set in a newly created locale object or modified in an existing object. The mask is constructed by a bitwise OR of the constants **LC_ADDRESS_MASK**, **LC_CTYPE_MASK**, **LC_COLLATE_MASK**, **LC_IDENTIFICATION_MASK**, **LC_MEASUREMENT_MASK**, **LC_MESSAGES_MASK**, **LC_MONETARY_MASK**, **LC_NUMERIC_MASK**, **LC_NAME_MASK**, **LC_PAPER_MASK**, **LC_TELEPHONE_MASK**, and **LC_TIME_MASK**. Alternatively, the mask can be specified as **LC_ALL_MASK**, which is equivalent to ORing all of the preceding constants.

For each category specified in *category_mask*, the locale data from *locale* will be used in the object returned by **newlocale**(). If a new locale object is being created, data for all categories not specified in *category_mask* is taken from the default ("POSIX") locale.

The following preset values of *locale* are defined for all categories that can be specified in *category_mask*:

"POSIX"
: A minimal locale environment for C language programs.

"C"
: Equivalent to "POSIX".

""
: An implementation-defined native environment corresponding to the values of the **LC_*** and **LANG** environment variables (see *locale*(7)).

freelocale()

The **freelocale**() function deallocates the resources associated with *locobj*, a locale object previously returned by a call to **newlocale**() or *duplocale*(3). If *locobj* is **LC_GLOBAL_LOCALE** or is not valid locale object handle, the results are undefined.

Once a locale object has been freed, the program should make no further use of it.

RETURN VALUE

On success, **newlocale**() returns a handle that can be used in calls to *duplocale*(3), **freelocale**(), and other functions that take a *locale_t* argument. On error, **newlocale**() returns *(locale_t) 0*, and sets *errno* to indicate the error.

ERRORS

EINVAL
One or more bits in *category_mask* do not correspond to a valid locale category.

EINVAL
locale is NULL.

ENOENT
locale is not a string pointer referring to a valid locale.

ENOMEM
Insufficient memory to create a locale object.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.3.

NOTES

Each locale object created by **newlocale**() should be deallocated using **freelocale**().

EXAMPLES

The program below takes up to two command-line arguments, which each identify locales. The first argument is required, and is used to set the **LC_NUMERIC** category in a locale object created using **newlocale**(). The second command-line argument is optional; if it is present, it is used to set the **LC_TIME** category of the locale object.

Having created and initialized the locale object, the program then applies it using *uselocale*(3), and then tests the effect of the locale changes by:

(1) Displaying a floating-point number with a fractional part. This output will be affected by the **LC_NUMERIC** setting. In many European-language locales, the fractional part of the number is separated from the integer part using a comma, rather than a period.

(2) Displaying the date. The format and language of the output will be affected by the **LC_TIME** setting.

The following shell sessions show some example runs of this program.

Set the **LC_NUMERIC** category to *fr_FR* (French):

```
$ ./a.out fr_FR
123456,789
Fri Mar  7 00:25:08 2014
```

Set the **LC_NUMERIC** category to *fr_FR* (French), and the **LC_TIME** category to *it_IT* (Italian):

```
$ ./a.out fr_FR it_IT
123456,789
ven 07 mar 2014 00:26:01 CET
```

Specify the **LC_TIME** setting as an empty string, which causes the value to be taken from environment variable settings (which, here, specify *mi_NZ*, New Zealand Māori):

```
$ LC_ALL=mi_NZ ./a.out fr_FR ""
123456,789
Te Paraire, te 07 o Poutū-te-rangi, 2014 00:38:44 CET
```

Program source

```
#define _XOPEN_SOURCE 700
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
```

```
#define errExit(msg)    do { perror(msg); exit(EXIT_FAILURE); \
                        } while (0)

int
main(int argc, char *argv[])
{
    char buf[100];
    time_t t;
    size_t s;
    struct tm *tm;
    locale_t loc, nloc;

    if (argc < 2) {
        fprintf(stderr, "Usage: %s locale1 [locale2]\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    /* Create a new locale object, taking the LC_NUMERIC settings
       from the locale specified in argv[1]. */

    loc = newlocale(LC_NUMERIC_MASK, argv[1], (locale_t) 0);
    if (loc == (locale_t) 0)
        errExit("newlocale");

    /* If a second command-line argument was specified, modify the
       locale object to take the LC_TIME settings from the locale
       specified in argv[2]. We assign the result of this newlocale()
       call to 'nloc' rather than 'loc', since in some cases, we might
       want to preserve 'loc' if this call fails. */

    if (argc > 2) {
        nloc = newlocale(LC_TIME_MASK, argv[2], loc);
        if (nloc == (locale_t) 0)
            errExit("newlocale");
        loc = nloc;
    }

    /* Apply the newly created locale to this thread. */

    uselocale(loc);

    /* Test effect of LC_NUMERIC. */

    printf("%8.3f\n", 123456.789);

    /* Test effect of LC_TIME. */

    t = time(NULL);
    tm = localtime(&t);
    if (tm == NULL)
        errExit("time");

    s = strftime(buf, sizeof(buf), "%c", tm);
    if (s == 0)
        errExit("strftime");

    printf("%s\n", buf);
```

```
        /* Free the locale object. */

        uselocale(LC_GLOBAL_LOCALE);    /* So 'loc' is no longer in use */
        freelocale(loc);

        exit(EXIT_SUCCESS);
    }
```

NAME

nextafter, nextafterf, nextafterl, nexttoward, nexttowardf, nexttowardl − floating-point number manipulation

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double nextafter(double x, double y);
float nextafterf(float x, float y);
long double nextafterl(long double x, long double y);

double nexttoward(double x, long double y);
float nexttowardf(float x, long double y);
long double nexttowardl(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

nextafter():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

nextafterf(), **nextafterl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

nexttoward(), **nexttowardf**(), **nexttowardl**():
_XOPEN_SOURCE >= 600 || _ISOC99_SOURCE
|| _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **nextafter**(), **nextafterf**(), and **nextafterl**() functions return the next representable floating-point value following *x* in the direction of *y*. If *y* is less than *x*, these functions will return the largest representable number less than *x*.

If *x* equals *y*, the functions return *y*.

The **nexttoward**(), **nexttowardf**(), and **nexttowardl**() functions do the same as the corresponding **nextafter**() functions, except that they have a *long double* second argument.

RETURN VALUE

On success, these functions return the next representable floating-point value after *x* in the direction of *y*.

If *x* equals *y*, then *y* (cast to the same type as *x*) is returned.

If *x* or *y* is a NaN, a NaN is returned.

If *x* is finite, and the result would overflow, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the correct mathematical sign.

If *x* is not equal to *y*, and the correct function result would be subnormal, zero, or underflow, a range error occurs, and either the correct value (if it can be represented), or 0.0, is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result overflow
errno is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error: result is subnormal or underflows
: *errno* is set to **ERANGE**. An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
nextafter(), **nextafterf**(), **nextafterl**(), **nexttoward**(), **nexttowardf**(), **nexttowardl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

This function is defined in IEC 559 (and the appendix with recommended functions in IEEE 754/IEEE 854).

HISTORY

C99, POSIX.1-2001.

BUGS

In glibc 2.5 and earlier, these functions do not raise an underflow floating-point (**FE_UNDERFLOW**) exception when an underflow occurs.

Before glibc 2.23 these functions did not set *errno*.

nearbyint(3)

NAME

nextup, nextupf, nextupl, nextdown, nextdownf, nextdownl − return next floating-point number toward positive/negative infinity

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#define _GNU_SOURCE     /* See feature_test_macros(7) */
#include <math.h>

double nextup(double x);
float nextupf(float x);
long double nextupl(long double x);

double nextdown(double x);
float nextdownf(float x);
long double nextdownl(long double x);
```

DESCRIPTION

The **nextup**(), **nextupf**(), and **nextupl**() functions return the next representable floating-point number greater than *x*.

If *x* is the smallest representable negative number in the corresponding type, these functions return −0. If *x* is 0, the returned value is the smallest representable positive number of the corresponding type.

If *x* is positive infinity, the returned value is positive infinity. If *x* is negative infinity, the returned value is the largest representable finite negative number of the corresponding type.

If *x* is Nan, the returned value is NaN.

The value returned by *nextdown(x)* is *−nextup(−x)*, and similarly for the other types.

RETURN VALUE

See DESCRIPTION.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
nextup(), **nextupf**(), **nextupl**(), **nextdown**(), **nextdownf**(), **nextdownl**()	Thread safety	MT-Safe

STANDARDS

NAME

nl_langinfo, nl_langinfo_l − query language and locale information

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <langinfo.h>

char *nl_langinfo(nl_item *item***);**
char *nl_langinfo_l(nl_item *item***, locale_t** *locale***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

nl_langinfo_l():
Since glibc 2.24:
_POSIX_C_SOURCE >= 200809L
glibc 2.23 and earlier:
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **nl_langinfo**() and **nl_langinfo_l**() functions provide access to locale information in a more flexible way than *localeconv*(3). **nl_langinfo**() returns a string which is the value corresponding to *item* in the program's current global locale. **nl_langinfo_l**() returns a string which is the value corresponding to *item* for the locale identified by the locale object *locale*, which was previously created by *newlocale*(3). Individual and additional elements of the locale categories can be queried.

Examples for the locale elements that can be specified in *item* using the constants defined in <*langinfo.h*> are:

CODESET (LC_CTYPE)
Return a string with the name of the character encoding used in the selected locale, such as "UTF−8", "ISO−8859−1", or "ANSI_X3.4−1968" (better known as US-ASCII). This is the same string that you get with "locale charmap". For a list of character encoding names, try "locale −m" (see *locale*(1)).

D_T_FMT (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) to represent time and date in a locale-specific way (**%c** conversion specification).

D_FMT (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) to represent a date in a locale-specific way (**%x** conversion specification).

T_FMT (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) to represent a time in a locale-specific way (**%X** conversion specification).

AM_STR (LC_TIME)
Return a string that represents affix for ante meridiem (before noon, "AM") time. (Used in **%p** *strftime*(3) conversion specification.)

PM_STR (LC_TIME)
Return a string that represents affix for post meridiem (before midnight, "PM") time. (Used in **%p** *strftime*(3) conversion specification.)

T_FMT_AMPM (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) to represent a time in a.m. or p.m. notation in a locale-specific way (**%r** conversion specification).

ERA (LC_TIME)
Return era description, which contains information about how years are counted and displayed for each era in a locale. Each era description segment shall have the format:

direction:*offset*:*start_date*:*end_date*:*era_name*:*era_format*

according to the definitions below:

direction Either a "+" or a "-" character. The "+" means that years increase from the *start_date* towards the *end_date*, " -" means the opposite.

offset The epoch year of the *start_date*.

start_date A date in the form *yyyy*/*mm*/*dd*, where *yyyy*, *mm*, and *dd* are the year, month, and day numbers respectively of the start of the era.

end_date The ending date of the era, in the same format as the *start_date*, or one of the two special values "**-***" (minus infinity) or "**+***" (plus infinity).

era_name The name of the era, corresponding to the **%EC** *strftime*(3) conversion specification.

era_format The format of the year in the era, corresponding to the **%EY** *strftime*(3) conversion specification.

Era description segments are separated by semicolons. Most locales do not define this value. Examples of locales that do define this value are the Japanese and Thai locales.

ERA_D_T_FMT (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) for alternative representation of time and date in a locale-specific way (**%Ec** conversion specification).

ERA_D_FMT (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) for alternative representation of a date in a locale-specific way (**%Ex** conversion specification).

ERA_T_FMT (LC_TIME)
Return a string that can be used as a format string for *strftime*(3) for alternative representation of a time in a locale-specific way (**%EX** conversion specification).

DAY_{1–7} (LC_TIME)
Return name of the *n*-th day of the week. [Warning: this follows the US convention DAY_1 = Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.] (Used in **%A** *strftime*(3) conversion specification.)

ABDAY_{1–7} (LC_TIME)
Return abbreviated name of the *n*-th day of the week. (Used in **%a** *strftime*(3) conversion specification.)

MON_{1–12} (LC_TIME)
Return name of the *n*-th month. (Used in **%B** *strftime*(3) conversion specification.)

ABMON_{1–12} (LC_TIME)
Return abbreviated name of the *n*-th month. (Used in **%b** *strftime*(3) conversion specification.)

RADIXCHAR (LC_NUMERIC)
Return radix character (decimal dot, decimal comma, etc.).

THOUSEP (LC_NUMERIC)
Return separator character for thousands (groups of three digits).

YESEXPR (LC_MESSAGES)
Return a regular expression that can be used with the *regex*(3) function to recognize a positive response to a yes/no question.

NOEXPR (LC_MESSAGES)
Return a regular expression that can be used with the *regex*(3) function to recognize a negative response to a yes/no question.

CRNCYSTR (LC_MONETARY)
Return the currency symbol, preceded by "−" if the symbol should appear before the value, "+" if the symbol should appear after the value, or "." if the symbol should replace the radix character.

The above list covers just some examples of items that can be requested. For a more detailed list, consult *The GNU C Library Reference Manual*.

RETURN VALUE

On success, these functions return a pointer to a string which is the value corresponding to *item* in the specified locale.

If no locale has been selected by *setlocale*(3) for the appropriate category, **nl_langinfo**() return a pointer to the corresponding string in the "C" locale. The same is true of **nl_langinfo_l**() if *locale* specifies a locale where *langinfo* data is not defined.

If *item* is not valid, a pointer to an empty string is returned.

The pointer returned by these functions may point to static data that may be overwritten, or the pointer itself may be invalidated, by a subsequent call to **nl_langinfo**(), **nl_langinfo_l**(), or *setlocale*(3). The same statements apply to **nl_langinfo_l**() if the locale object referred to by *locale* is freed or modified by *freelocale*(3) or *newlocale*(3).

POSIX specifies that the application may not modify the string returned by these functions.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
nl_langinfo()	Thread safety	MT-Safe locale

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SUSv2.

NOTES

The behavior of **nl_langinfo_l**() is undefined if *locale* is the special locale object **LC_GLOBAL_LOCALE** or is not a valid locale object handle.

EXAMPLES

The following program sets the character type and the numeric locale according to the environment and queries the terminal character set and the radix character.

```
#include <langinfo.h>
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    setlocale(LC_CTYPE, "");
    setlocale(LC_NUMERIC, "");

    printf("%s\n", nl_langinfo(CODESET));
    printf("%s\n", nl_langinfo(RADIXCHAR));

    exit(EXIT_SUCCESS);
}
```

NAME

ntp_gettime, ntp_gettimex − get time parameters (NTP daemon interface)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/timex.h>

int ntp_gettime(struct ntptimeval ****ntv*);**
int ntp_gettimex(struct ntptimeval ****ntv*);**

DESCRIPTION

Both of these APIs return information to the caller via the *ntv* argument, a structure of the following type:

```
struct ntptimeval {
    struct timeval time;    /* Current time */
    long maxerror;          /* Maximum error */
    long esterror;          /* Estimated error */
    long tai;               /* TAI offset */

    /* Further padding bytes allowing for future expansion */
};
```

The fields of this structure are as follows:

time The current time, expressed as a *timeval* structure:

```
struct timeval {
    time_t      tv_sec;   /* Seconds since the Epoch */
    suseconds_t tv_usec;  /* Microseconds */
};
```

maxerror
: Maximum error, in microseconds. This value can be initialized by *ntp_adjtime*(3), and is increased periodically (on Linux: each second), but is clamped to an upper limit (the kernel constant **NTP_PHASE_MAX**, with a value of 16,000).

esterror
: Estimated error, in microseconds. This value can be set via *ntp_adjtime*(3) to contain an estimate of the difference between the system clock and the true time. This value is not used inside the kernel.

tai TAI (Atomic International Time) offset.

ntp_gettime() returns an *ntptimeval* structure in which the *time*, *maxerror*, and *esterror* fields are filled in.

ntp_gettimex() performs the same task as **ntp_gettime**(), but also returns information in the *tai* field.

RETURN VALUE

The return values for **ntp_gettime**() and **ntp_gettimex**() are as for *adjtimex*(2). Given a correct pointer argument, these functions always succeed.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NTP "Kernel Application Program Interface"

NAME

offsetof − offset of a structure member

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stddef.h>

size_t offsetof(*type***,** *member***);**

DESCRIPTION

The macro **offsetof**() returns the offset of the field *member* from the start of the structure *type*.

This macro is useful because the sizes of the fields that compose a structure can vary across implementations, and compilers may insert different numbers of padding bytes between fields. Consequently, an element's offset is not necessarily given by the sum of the sizes of the previous elements.

A compiler error will result if *member* is not aligned to a byte boundary (i.e., it is a bit field).

RETURN VALUE

offsetof() returns the offset of the given *member* within the given *type*, in units of bytes.

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89.

EXAMPLES

On a Linux/i386 system, when compiled using the default *gcc*(1) options, the program below produces the following output:

```
$ ./a.out
offsets: i=0; c=4; d=8 a=16
sizeof(struct s)=16
```

Program source

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    struct s {
        int i;
        char c;
        double d;
        char a[];
    };

    /* Output is compiler dependent */

    printf("offsets: i=%zu; c=%zu; d=%zu a=%zu\n",
           offsetof(struct s, i), offsetof(struct s, c),
           offsetof(struct s, d), offsetof(struct s, a));
    printf("sizeof(struct s)=%zu\n", sizeof(struct s));

    exit(EXIT_SUCCESS);
}
```

NAME

on_exit − register a function to be called at normal process termination

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int on_exit(void (* *function*)(int, void *), void **arg*);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

on_exit():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **on_exit**() function registers the given *function* to be called at normal process termination, whether via *exit*(3) or via return from the program's *main*(). The *function* is passed the status argument given to the last call to *exit*(3) and the *arg* argument from **on_exit**().

The same function may be registered multiple times: it is called once for each registration.

When a child process is created via *fork*(2), it inherits copies of its parent's registrations. Upon a successful call to one of the *exec*(3) functions, all registrations are removed.

RETURN VALUE

The **on_exit**() function returns the value 0 if successful; otherwise it returns a nonzero value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
on_exit()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

SunOS 4, glibc. Removed in Solaris (SunOS 5). Use the standard *atexit*(3) instead.

CAVEATS

By the time *function* is executed, stack (*auto*) variables may already have gone out of scope. Therefore, *arg* should not be a pointer to a stack variable; it may however be a pointer to a heap variable or a global variable.

SEE ALSO

_exit(2), *atexit*(3), *exit*(3)

NAME

open_memstream, open_wmemstream − open a dynamic memory buffer stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

FILE *open_memstream(char **ptr, size_t *sizeloc);

#include <wchar.h>

FILE *open_wmemstream(wchar_t **ptr, size_t *sizeloc);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

open_memstream(), **open_wmemstream**():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **open_memstream**() function opens a stream for writing to a memory buffer. The function dynamically allocates the buffer, and the buffer automatically grows as needed. Initially, the buffer has a size of zero. After closing the stream, the caller should *free*(3) this buffer.

The locations pointed to by *ptr* and *sizeloc* are used to report, respectively, the current location and the size of the buffer. The locations referred to by these pointers are updated each time the stream is flushed (**fflush**(3)) and when the stream is closed (**fclose**(3)). These values remain valid only as long as the caller performs no further output on the stream. If further output is performed, then the stream must again be flushed before trying to access these values.

A null byte is maintained at the end of the buffer. This byte is *not* included in the size value stored at *sizeloc*.

The stream maintains the notion of a current position, which is initially zero (the start of the buffer). Each write operation implicitly adjusts the buffer position. The stream's buffer position can be explicitly changed with *fseek*(3) or *fseeko*(3). Moving the buffer position past the end of the data already written fills the intervening space with null characters.

The **open_wmemstream**() is similar to **open_memstream**(), but operates on wide characters instead of bytes.

RETURN VALUE

Upon successful completion, **open_memstream**() and **open_wmemstream**() return a *FILE* pointer. Otherwise, NULL is returned and *errno* is set to indicate the error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
open_memstream(), **open_wmemstream**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

open_memstream()
glibc 1.0.x.

open_wmemstream()
glibc 2.4.

NOTES

There is no file descriptor associated with the file stream returned by these functions (i.e., *fileno*(3) will return an error if called on the returned stream).

BUGS

Before glibc 2.7, seeking past the end of a stream created by **open_memstream**() does not enlarge the buffer; instead the *fseek*(3) call fails, returning −1.

EXAMPLES

See *fmemopen*(3).

SEE ALSO

fmemopen(3), *fopen*(3), *setbuf*(3)

NAME

opendir, fdopendir − open a directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/types.h>
#include <dirent.h>

DIR *opendir(const char *name);
DIR *fdopendir(int fd);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

fdopendir():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **opendir**() function opens a directory stream corresponding to the directory *name*, and returns a pointer to the directory stream. The stream is positioned at the first entry in the directory.

The **fdopendir**() function is like **opendir**(), but returns a directory stream for the directory referred to by the open file descriptor *fd*. After a successful call to **fdopendir**(), *fd* is used internally by the implementation, and should not otherwise be used by the application.

RETURN VALUE

The **opendir**() and **fdopendir**() functions return a pointer to the directory stream. On error, NULL is returned, and *errno* is set to indicate the error.

ERRORS

EACCES
Permission denied.

EBADF
fd is not a valid file descriptor opened for reading.

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOENT
Directory does not exist, or *name* is an empty string.

ENOMEM
Insufficient memory to complete the operation.

ENOTDIR
name is not a directory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
opendir(), **fdopendir**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

STANDARDS

opendir()
SVr4, 4.3BSD, POSIX.1-2001.

fdopendir()
POSIX.1-2008. glibc 2.4.

NOTES

Filename entries can be read from a directory stream using *readdir*(3).

The underlying file descriptor of the directory stream can be obtained using *dirfd*(3).

The **opendir**() function sets the close-on-exec flag for the file descriptor underlying the *DIR* *. The **fdopendir**() function leaves the setting of the close-on-exec flag unchanged for the file descriptor, *fd*. POSIX.1-200x leaves it unspecified whether a successful call to **fdopendir**() will set the close-on-exec flag for the file descriptor, *fd*.

SEE ALSO

open(2), *closedir*(3), *dirfd*(3), *readdir*(3), *rewinddir*(3), *scandir*(3), *seekdir*(3), *telldir*(3)

NAME

openpty, login_tty, forkpty − terminal utility functions

LIBRARY

System utilities library (*libutil*, −*lutil*)

SYNOPSIS

```
#include <pty.h>

int openpty(int *amaster, int *aslave, char *name,
        const struct termios *termp,
        const struct winsize *winp);
pid_t forkpty(int *amaster, char *name,
        const struct termios *termp,
        const struct winsize *winp);

#include <utmp.h>

int login_tty(int fd);
```

DESCRIPTION

The **openpty**() function finds an available pseudoterminal and returns file descriptors for the master and slave in *amaster* and *aslave*. If *name* is not NULL, the filename of the slave is returned in *name*. If *termp* is not NULL, the terminal parameters of the slave will be set to the values in *termp*. If *winp* is not NULL, the window size of the slave will be set to the values in *winp*.

The **login_tty**() function prepares for a login on the terminal referred to by the file descriptor *fd* (which may be a real terminal device, or the slave of a pseudoterminal as returned by *openpty*()) by creating a new session, making *fd* the controlling terminal for the calling process, setting *fd* to be the standard input, output, and error streams of the current process, and closing *fd*.

The **forkpty**() function combines **openpty**(), *fork*(2), and **login_tty**() to create a new process operating in a pseudoterminal. A file descriptor referring to master side of the pseudoterminal is returned in *amaster*. If *name* is not NULL, the buffer it points to is used to return the filename of the slave. The *termp* and *winp* arguments, if not NULL, will determine the terminal attributes and window size of the slave side of the pseudoterminal.

RETURN VALUE

If a call to **openpty**(), **login_tty**(), or **forkpty**() is not successful, −1 is returned and *errno* is set to indicate the error. Otherwise, **openpty**(), **login_tty**(), and the child process of **forkpty**() return 0, and the parent process of **forkpty**() returns the process ID of the child process.

ERRORS

openpty() fails if:

ENOENT
There are no available terminals.

login_tty() fails if *ioctl*(2) fails to set *fd* to the controlling terminal of the calling process.

forkpty() fails if either **openpty**() or *fork*(2) fails.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
forkpty(), **openpty**()	Thread safety	MT-Safe locale
login_tty()	Thread safety	MT-Unsafe race:ttyname

STANDARDS

BSD.

HISTORY

The **const** modifiers were added to the structure pointer arguments of **openpty**() and **forkpty**() in glibc 2.8.

Before glibc 2.0.92, **openpty**() returns file descriptors for a BSD pseudoterminal pair; since glibc 2.0.92, it first attempts to open a UNIX 98 pseudoterminal pair, and falls back to opening a BSD pseudoterminal pair if that fails.

BUGS

Nobody knows how much space should be reserved for *name*. So, calling **openpty**() or **forkpty**() with non-NULL *name* may not be secure.

SEE ALSO

fork(2), *ttyname*(3), *pty*(7)

NAME

perror − print a system error message

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

void perror(const char *s);

#include <errno.h>

int errno;      /* Not really declared this way; see errno(3) */

[[deprecated]] const char *const sys_errlist[];
[[deprecated]] int sys_nerr;
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sys_errlist, *sys_nerr*:
From glibc 2.19 to glibc 2.31:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The **perror**() function produces a message on standard error describing the last error encountered during a call to a system or library function.

First (if *s* is not NULL and **s* is not a null byte ('\0')), the argument string *s* is printed, followed by a colon and a blank. Then an error message corresponding to the current value of *errno* and a new-line.

To be of most use, the argument string should include the name of the function that incurred the error.

The global error list *sys_errlist*[], which can be indexed by *errno*, can be used to obtain the error message without the newline. The largest message number provided in the table is *sys_nerr*−1. Be careful when directly accessing this list, because new error values may not have been added to *sys_errlist*[]. The use of *sys_errlist*[] is nowadays deprecated; use *strerror*(3) instead.

When a system call fails, it usually returns −1 and sets the variable *errno* to a value describing what went wrong. (These values can be found in <*errno.h*>.) Many library functions do likewise. The function **perror**() serves to translate this error code into human-readable form. Note that *errno* is undefined after a successful system call or library function call: this call may well change this variable, even though it succeeds, for example because it internally used some other library function that failed. Thus, if a failing call is not immediately followed by a call to **perror**(), the value of *errno* should be saved.

ATTRIBUTES

NAME

popen, pclose − pipe stream to or from a process

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

FILE *popen(const char *command, const char *type);
int pclose(FILE *stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

popen(), **pclose**():
_POSIX_C_SOURCE >= 2
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **popen**() function opens a process by creating a pipe, forking, and invoking the shell. Since a pipe is by definition unidirectional, the *type* argument may specify only reading or writing, not both; the resulting stream is correspondingly read-only or write-only.

The *command* argument is a pointer to a null-terminated string containing a shell command line. This command is passed to */bin/sh* using the **−c** flag; interpretation, if any, is performed by the shell.

The *type* argument is a pointer to a null-terminated string which must contain either the letter 'r' for reading or the letter 'w' for writing. Since glibc 2.9, this argument can additionally include the letter 'e', which causes the close-on-exec flag (**FD_CLOEXEC**) to be set on the underlying file descriptor; see the description of the **O_CLOEXEC** flag in *open*(2) for reasons why this may be useful.

The return value from **popen**() is a normal standard I/O stream in all respects save that it must be closed with **pclose**() rather than *fclose*(3). Writing to such a stream writes to the standard input of the command; the command's standard output is the same as that of the process that called **popen**(), unless this is altered by the command itself. Conversely, reading from the stream reads the command's standard output, and the command's standard input is the same as that of the process that called **popen**().

Note that output **popen**() streams are block buffered by default.

The **pclose**() function waits for the associated process to terminate and returns the exit status of the command as returned by *wait4*(2).

RETURN VALUE

popen(): on success, returns a pointer to an open stream that can be used to read or write to the pipe; if the *fork*(2) or *pipe*(2) calls fail, or if the function cannot allocate memory, NULL is returned.

pclose(): on success, returns the exit status of the command; if *wait4*(2) returns an error, or some other error is detected, −1 is returned.

On failure, both functions set *errno* to indicate the error.

ERRORS

The **popen**() function does not set *errno* if memory allocation fails. If the underlying *fork*(2) or *pipe*(2) fails, *errno* is set to indicate the error. If the *type* argument is invalid, and this condition is detected, *errno* is set to **EINVAL**.

If **pclose**() cannot obtain the child status, *errno* is set to **ECHILD**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
popen(), **pclose**()	Thread safety	MT-Safe

VERSIONS

The 'e' value for *type* is a Linux extension.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

CAVEATS

Carefully read Caveats in *system*(3).

BUGS

Since the standard input of a command opened for reading shares its seek offset with the process that called **popen**(), if the original process has done a buffered read, the command's input position may not be as expected. Similarly, the output from a command opened for writing may become intermingled with that of the original process. The latter can be avoided by calling *fflush*(3) before **popen**().

Failure to execute the shell is indistinguishable from the shell's failure to execute the command, or an immediate exit of the command. The only hint is an exit status of 127.

SEE ALSO

sh(1), *fork*(2), *pipe*(2), *wait4*(2), *fclose*(3), *fflush*(3), *fopen*(3), *stdio*(3), *system*(3)

NAME

posix_fallocate − allocate file space

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <fcntl.h>

int posix_fallocate(int fd, off_t offset, off_t len);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

posix_fallocate():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

The function **posix_fallocate**() ensures that disk space is allocated for the file referred to by the file descriptor *fd* for the bytes in the range starting at *offset* and continuing for *len* bytes. After a successful call to **posix_fallocate**(), subsequent writes to bytes in the specified range are guaranteed not to fail because of lack of disk space.

If the size of the file is less than *offset*+*len*, then the file is increased to this size; otherwise the file size is left unchanged.

RETURN VALUE

posix_fallocate() returns zero on success, or an error number on failure. Note that *errno* is not set.

ERRORS

EBADF
fd is not a valid file descriptor, or is not opened for writing.

EFBIG
offset+*len* exceeds the maximum file size.

EINTR
A signal was caught during execution.

EINVAL
offset was less than 0, or *len* was less than or equal to 0, or the underlying filesystem does not support the operation.

ENODEV
fd does not refer to a regular file.

ENOSPC
There is not enough space left on the device containing the file referred to by *fd*.

EOPNOTSUPP
The filesystem containing the file referred to by *fd* does not support this operation. This error code can be returned by C libraries that don't perform the emulation shown in NOTES, such as musl libc.

ESPIPE
fd refers to a pipe.

ATTRIBUTES

Interface	Attribute	Value
posix_fallocate()	Thread safety	MT-Safe (but see NOTES)

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1.94. POSIX.1-2001

POSIX.1-2008 says that an implementation *shall* give the **EINVAL** error if *len* was 0, or *offset* was less than 0. POSIX.1-2001 says that an implementation *shall* give the **EINVAL** error if *len* is less than 0, or *offset* was less than 0, and *may* give the error if *len* equals zero.

CAVEATS

In the glibc implementation, **posix_fallocate**() is implemented using the *fallocate*(2) system call, which is MT-safe. If the underlying filesystem does not support *fallocate*(2), then the operation is emulated with the following caveats:

- The emulation is inefficient.
- There is a race condition where concurrent writes from another thread or process could be overwritten with null bytes.
- There is a race condition where concurrent file size increases by another thread or process could result in a file whose size is smaller than expected.
- If *fd* has been opened with the **O_APPEND** or **O_WRONLY** flags, the function fails with the error **EBADF**.

In general, the emulation is not MT-safe. On Linux, applications may use *fallocate*(2) if they cannot tolerate the emulation caveats. In general, this is only recommended if the application plans to terminate the operation if **EOPNOTSUPP** is returned, otherwise the application itself will need to implement a fallback with all the same problems as the emulation provided by glibc.

NAME

posix_madvise − give advice about patterns of memory usage

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/mman.h>

int posix_madvise(void *addr***[.***len***], size_t** *len***, int** *advice***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

posix_madvise():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **posix_madvise**() function allows an application to advise the system about its expected patterns of usage of memory in the address range starting at *addr* and continuing for *len* bytes. The system is free to use this advice in order to improve the performance of memory accesses (or to ignore the advice altogether), but calling **posix_madvise**() shall not affect the semantics of access to memory in the specified range.

The *advice* argument is one of the following:

POSIX_MADV_NORMAL
The application has no special advice regarding its memory usage patterns for the specified address range. This is the default behavior.

POSIX_MADV_SEQUENTIAL
The application expects to access the specified address range sequentially, running from lower addresses to higher addresses. Hence, pages in this region can be aggressively read ahead, and may be freed soon after they are accessed.

POSIX_MADV_RANDOM
The application expects to access the specified address range randomly. Thus, read ahead may be less useful than normally.

POSIX_MADV_WILLNEED
The application expects to access the specified address range in the near future. Thus, read ahead may be beneficial.

POSIX_MADV_DONTNEED
The application expects that it will not access the specified address range in the near future.

RETURN VALUE

On success, **posix_madvise**() returns 0. On failure, it returns a positive error number.

ERRORS

EINVAL
addr is not a multiple of the system page size or *len* is negative.

EINVAL
advice is invalid.

ENOMEM
Addresses in the specified range are partially or completely outside the caller's address space.

VERSIONS

POSIX.1 permits an implementation to generate an error if *len* is 0. On Linux, specifying *len* as 0 is permitted (as a successful no-op).

In glibc, this function is implemented using *madvise*(2). However, since glibc 2.6, **POSIX_MADV_DONTNEED** is treated as a no-op, because the corresponding *madvise*(2) value, **MADV_DONTNEED**, has destructive semantics.

NAME

posix_memalign, aligned_alloc, memalign, valloc, pvalloc − allocate aligned memory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int posix_memalign(void **memptr, size_t alignment, size_t size);
void *aligned_alloc(size_t alignment, size_t size);
[[deprecated]] void *valloc(size_t size);

#include <malloc.h>

[[deprecated]] void *memalign(size_t alignment, size_t size);
[[deprecated]] void *pvalloc(size_t size);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

posix_memalign():
_POSIX_C_SOURCE >= 200112L

aligned_alloc():
_ISOC11_SOURCE

valloc():
Since glibc 2.12:
(_XOPEN_SOURCE >= 500) && !(_POSIX_C_SOURCE >= 200112L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE
Before glibc 2.12:
_BSD_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

posix_memalign() allocates *size* bytes and places the address of the allocated memory in **memptr*. The address of the allocated memory will be a multiple of *alignment*, which must be a power of two and a multiple of *sizeof(void *)*. This address can later be successfully passed to *free*(3). If *size* is 0, then the value placed in **memptr* is either NULL or a unique pointer value.

The obsolete function **memalign**() allocates *size* bytes and returns a pointer to the allocated memory. The memory address will be a multiple of *alignment*, which must be a power of two.

aligned_alloc() is the same as **memalign**(), except for the added restriction that *alignment* must be a power of two.

The obsolete function **valloc**() allocates *size* bytes and returns a pointer to the allocated memory. The memory address will be a multiple of the page size. It is equivalent to *memalign(sysconf(_SC_PAGESIZE),size)*.

The obsolete function **pvalloc**() is similar to **valloc**(), but rounds the size of the allocation up to the next multiple of the system page size.

For all of these functions, the memory is not zeroed.

RETURN VALUE

aligned_alloc(), **memalign**(), **valloc**(), and **pvalloc**() return a pointer to the allocated memory on success. On error, NULL is returned, and *errno* is set to indicate the error.

posix_memalign() returns zero on success, or one of the error values listed in the next section on failure. The value of *errno* is not set. On Linux (and other systems), **posix_memalign**() does not modify *memptr* on failure. A requirement standardizing this behavior was added in POSIX.1-2008 TC2.

ERRORS

EINVAL
The *alignment* argument was not a power of two, or was not a multiple of *sizeof(void *)*.

ENOMEM
Out of memory.

valloc()
: glibc 2.0. 3.0BSD. Documented as obsolete in 4.3BSD, and as legacy in SUSv2.

pvalloc()
: glibc 2.0.

Headers

Everybody agrees that **posix_memalign**() is declared in <*stdlib.h*>.

On some systems **memalign**() is declared in <*stdlib.h*> instead of <*malloc.h*>.

According to SUSv2, **valloc**() is declared in <*stdlib.h*>. glibc declares it in <*malloc.h*>, and also in <*stdlib.h*> if suitable feature test macros are defined (see above).

NOTES

On many systems there are alignment restrictions, for example, on buffers used for direct block device I/O. POSIX specifies the *pathconf(path,_PC_REC_XFER_ALIGN)* call that tells what alignment is needed. Now one can use **posix_memalign**() to satisfy this requirement.

posix_memalign() verifies that *alignment* matches the requirements detailed above. **memalign**() may not check that the *alignment* argument is correct.

POSIX requires that memory obtained from **posix_memalign**() can be freed using *free*(3). Some systems provide no way to reclaim memory allocated with **memalign**() or **valloc**() (because one can pass to *free*(3) only a pointer obtained from *malloc*(3), while, for example, **memalign**() would call *malloc*(3) and then align the obtained value). The glibc implementation allows memory obtained from any of these functions to be reclaimed with *free*(3).

The glibc *malloc*(3) always returns 8-byte aligned memory addresses, so these functions are needed only if you require larger alignment values.

NAME

posix_openpt − open a pseudoterminal device

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>
#include <fcntl.h>

int posix_openpt(int flags);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

posix_openpt():
_XOPEN_SOURCE >= 600

DESCRIPTION

The **posix_openpt**() function opens an unused pseudoterminal master device, returning a file descriptor that can be used to refer to that device.

The *flags* argument is a bit mask that ORs together zero or more of the following flags:

O_RDWR
Open the device for both reading and writing. It is usual to specify this flag.

O_NOCTTY
Do not make this device the controlling terminal for the process.

RETURN VALUE

On success, **posix_openpt**() returns a file descriptor (a nonnegative integer) which is the lowest numbered unused file descriptor. On failure, −1 is returned, and *errno* is set to indicate the error.

ERRORS

See *open*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
posix_openpt()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2.1. POSIX.1-2001.

It is part of the UNIX 98 pseudoterminal support (see *pts*(4)).

NOTES

Some older UNIX implementations that support System V (aka UNIX 98) pseudoterminals don't have this function, but it can be easily implemented by opening the pseudoterminal multiplexor device:

```
int
posix_openpt(int flags)
{
    return open("/dev/ptmx", flags);
}
```

Calling **posix_openpt**() creates a pathname for the corresponding pseudoterminal slave device. The pathname of the slave device can be obtained using *ptsname*(3). The slave device pathname exists only as long as the master device is open.

NAME

posix_spawn, posix_spawnp − spawn a process

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <spawn.h>

int posix_spawn(pid_t *restrict pid, const char *restrict path,
        const posix_spawn_file_actions_t *restrict file_actions,
        const posix_spawnattr_t *restrict attrp,
        char *const argv[restrict],
        char *const envp[restrict]);
int posix_spawnp(pid_t *restrict pid, const char *restrict file,
        const posix_spawn_file_actions_t *restrict file_actions,
        const posix_spawnattr_t *restrict attrp,
        char *const argv[restrict],
        char *const envp[restrict]);
```

DESCRIPTION

The **posix_spawn**() and **posix_spawnp**() functions are used to create a new child process that executes a specified file. These functions were specified by POSIX to provide a standardized method of creating new processes on machines that lack the capability to support the *fork*(2) system call. These machines are generally small, embedded systems lacking MMU support.

The **posix_spawn**() and **posix_spawnp**() functions provide the functionality of a combined *fork*(2) and *exec*(3), with some optional housekeeping steps in the child process before the *exec*(3). These functions are not meant to replace the *fork*(2) and *execve*(2) system calls. In fact, they provide only a subset of the functionality that can be achieved by using the system calls.

The only difference between **posix_spawn**() and **posix_spawnp**() is the manner in which they specify the file to be executed by the child process. With **posix_spawn**(), the executable file is specified as a pathname (which can be absolute or relative). With **posix_spawnp**(), the executable file is specified as a simple filename; the system searches for this file in the list of directories specified by **PATH** (in the same way as for *execvp*(3)). For the remainder of this page, the discussion is phrased in terms of **posix_spawn**(), with the understanding that **posix_spawnp**() differs only on the point just described.

The remaining arguments to these two functions are as follows:

pid points to a buffer that is used to return the process ID of the new child process.

file_actions
: points to a *spawn file actions object* that specifies file-related actions to be performed in the child between the *fork*(2) and *exec*(3) steps. This object is initialized and populated before the **posix_spawn**() call using *posix_spawn_file_actions_init*(3) and the **posix_spawn_file_actions_***() functions.

attrp points to an *attributes objects* that specifies various attributes of the created child process. This object is initialized and populated before the **posix_spawn**() call using *posix_spawnattr_init*(3) and the **posix_spawnattr_***() functions.

argv
envp specify the argument list and environment for the program that is executed in the child process, as for *execve*(2).

Below, the functions are described in terms of a three-step process: the **fork**() step, the pre-**exec**() step (executed in the child), and the **exec**() step (executed in the child).

fork() step

Since glibc 2.24, the **posix_spawn**() function commences by calling *clone*(2) with **CLONE_VM** and **CLONE_VFORK** flags. Older implementations use *fork*(2), or possibly *vfork*(2) (see below).

The PID of the new child process is placed in **pid*. The **posix_spawn**() function then returns control to the parent process.

Subsequently, the parent can use one of the system calls described in *wait*(2) to check the status of the child process. If the child fails in any of the housekeeping steps described below, or fails to execute the

desired file, it exits with a status of 127.

Before glibc 2.24, the child process is created using *vfork*(2) instead of *fork*(2) when either of the following is true:

- the *spawn-flags* element of the attributes object pointed to by *attrp* contains the GNU-specific flag **POSIX_SPAWN_USEVFORK**; or
- *file_actions* is NULL and the *spawn-flags* element of the attributes object pointed to by *attrp* does *not* contain **POSIX_SPAWN_SETSIGMASK**, **POSIX_SPAWN_SETSIGDEF**, **POSIX_SPAWN_SETSCHEDPARAM**, **POSIX_SPAWN_SETSCHEDULER**, **POSIX_SPAWN_SETPGROUP**, or **POSIX_SPAWN_RESETIDS**.

In other words, *vfork*(2) is used if the caller requests it, or if there is no cleanup expected in the child before it *exec*(3)s the requested file.

pre-exec() step: housekeeping

In between the **fork()** and the **exec()** steps, a child process may need to perform a set of housekeeping actions. The **posix_spawn**() and **posix_spawnp**() functions support a small, well-defined set of system tasks that the child process can accomplish before it executes the executable file. These operations are controlled by the attributes object pointed to by *attrp* and the file actions object pointed to by *file_actions*. In the child, processing is done in the following sequence:

(1) Process attribute actions: signal mask, signal default handlers, scheduling algorithm and parameters, process group, and effective user and group IDs are changed as specified by the attributes object pointed to by *attrp*.

(2) File actions, as specified in the *file_actions* argument, are performed in the order that they were specified using calls to the **posix_spawn_file_actions_add***() functions.

(3) File descriptors with the **FD_CLOEXEC** flag set are closed.

All process attributes in the child, other than those affected by attributes specified in the object pointed to by *attrp* and the file actions in the object pointed to by *file_actions*, will be affected as though the child was created with *fork*(2) and it executed the program with *execve*(2).

The process attributes actions are defined by the attributes object pointed to by *attrp*. The *spawn-flags* attribute (set using *posix_spawnattr_setflags*(3)) controls the general actions that occur, and other attributes in the object specify values to be used during those actions.

The effects of the flags that may be specified in *spawn-flags* are as follows:

POSIX_SPAWN_SETSIGMASK
Set the signal mask to the signal set specified in the *spawn-sigmask* attribute of the object pointed to by *attrp*. If the **POSIX_SPAWN_SETSIGMASK** flag is not set, then the child inherits the parent's signal mask.

POSIX_SPAWN_SETSIGDEF
Reset the disposition of all signals in the set specified in the *spawn-sigdefault* attribute of the object pointed to by *attrp* to the default. For the treatment of the dispositions of signals not specified in the *spawn-sigdefault* attribute, or the treatment when **POSIX_SPAWN_SETSIGDEF** is not specified, see *execve*(2).

POSIX_SPAWN_SETSCHEDPARAM
If this flag is set, and the **POSIX_SPAWN_SETSCHEDULER** flag is not set, then set the scheduling parameters to the parameters specified in the *spawn-schedparam* attribute of the object pointed to by *attrp*.

POSIX_SPAWN_SETSCHEDULER
Set the scheduling policy algorithm and parameters of the child, as follows:

- The scheduling policy is set to the value specified in the *spawn-schedpolicy* attribute of the object pointed to by *attrp*.
- The scheduling parameters are set to the value specified in the *spawn-schedparam* attribute of the object pointed to by *attrp* (but see BUGS).

If the **POSIX_SPAWN_SETSCHEDPARAM** and **POSIX_SPAWN_SETSCHEDPOLICY** flags are not specified, the child inherits the corresponding scheduling attributes from the

parent.

POSIX_SPAWN_RESETIDS
If this flag is set, reset the effective UID and GID to the real UID and GID of the parent process. If this flag is not set, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file, their effect will override the setting of the effective UID and GID (se *execve*(2)).

POSIX_SPAWN_SETPGROUP
Set the process group to the value specified in the *spawn-pgroup* attribute of the object pointed to by *attrp*. If the *spawn-pgroup* attribute has the value 0, the child's process group ID is made the same as its process ID. If the **POSIX_SPAWN_SETPGROUP** flag is not set, the child inherits the parent's process group ID.

POSIX_SPAWN_USEVFORK
Since glibc 2.24, this flag has no effect. On older implementations, setting this flag forces the **fork()** step to use *vfork*(2) instead of *fork*(2). The **_GNU_SOURCE** feature test macro must be defined to obtain the definition of this constant.

POSIX_SPAWN_SETSID (since glibc 2.26)
If this flag is set, the child process shall create a new session and become the session leader. The child process shall also become the process group leader of the new process group in the session (see *setsid*(2)). The **_GNU_SOURCE** feature test macro must be defined to obtain the definition of this constant.

If *attrp* is NULL, then the default behaviors described above for each flag apply.

The *file_actions* argument specifies a sequence of file operations that are performed in the child process after the general processing described above, and before it performs the *exec*(3). If *file_actions* is NULL, then no special action is taken, and standard *exec*(3) semantics apply—file descriptors open before the exec remain open in the new process, except those for which the **FD_CLOEXEC** flag has been set. File locks remain in place.

If *file_actions* is not NULL, then it contains an ordered set of requests to *open*(2), *close*(2), and *dup2*(2) files. These requests are added to the *file_actions* by *posix_spawn_file_actions_addopen*(3), *posix_spawn_file_actions_addclose*(3), and *posix_spawn_file_actions_adddup2*(3)The requested operations are performed in the order they were added to *file_actions*.

If any of the housekeeping actions fails (due to bogus values being passed or other reasons why signal handling, process scheduling, process group ID functions, and file descriptor operations might fail), the child process exits with exit value 127.

exec() step
Once the child has successfully forked and performed all requested pre-exec steps, the child runs the requested executable.

The child process takes its environment from the *envp* argument, which is interpreted as if it had been passed to *execve*(2). The arguments to the created process come from the *argv* argument, which is processed as for *execve*(2).

RETURN VALUE

Upon successful completion, **posix_spawn**() and **posix_spawnp**() place the PID of the child process in *pid*, and return 0. If there is an error during the **fork()** step, then no child is created, the contents of **pid* are unspecified, and these functions return an error number as described below.

Even when these functions return a success status, the child process may still fail for a plethora of reasons related to its pre-**exec**() initialization. In addition, the *exec*(3) may fail. In all of these cases, the child process will exit with the exit value of 127.

ERRORS

The **posix_spawn**() and **posix_spawnp**() functions fail only in the case where the underlying *fork*(2), *vfork*(2), or *clone*(2) call fails; in these cases, these functions return an error number, which will be one of the errors described for *fork*(2), *vfork*(2), or *clone*(2).

In addition, these functions fail if:

ENOSYS
Function not supported on this system.

STANDARDS
POSIX.1-2008.

HISTORY
glibc 2.2. POSIX.1-2001.

NOTES
The housekeeping activities in the child are controlled by the objects pointed to by *attrp* (for non-file actions) and *file_actions* In POSIX parlance, the *posix_spawnattr_t* and *posix_spawn_file_actions_t* data types are referred to as objects, and their elements are not specified by name. Portable programs should initialize these objects using only the POSIX-specified functions. (In other words, although these objects may be implemented as structures containing fields, portable programs must avoid dependence on such implementation details.)

According to POSIX, it is unspecified whether fork handlers established with *pthread_atfork*(3) are called when **posix_spawn**() is invoked. Since glibc 2.24, the fork handlers are not executed in any case. On older implementations, fork handlers are called only if the child is created using *fork*(2).

There is no "posix_fspawn" function (i.e., a function that is to **posix_spawn**() as *fexecve*(3) is to *execve*(2)). However, this functionality can be obtained by specifying the *path* argument as one of the files in the caller's */proc/self/fd* directory.

BUGS
POSIX.1 says that when **POSIX_SPAWN_SETSCHEDULER** is specified in *spawn-flags*, then the **POSIX_SPAWN_SETSCHEDPARAM** (if present) is ignored. However, before glibc 2.14, calls to **posix_spawn**() failed with an error if **POSIX_SPAWN_SETSCHEDULER** was specified without also specifying **POSIX_SPAWN_SETSCHEDPARAM**.

EXAMPLES
The program below demonstrates the use of various functions in the POSIX spawn API. The program accepts command-line attributes that can be used to create file actions and attributes objects. The remaining command-line arguments are used as the executable name and command-line arguments of the program that is executed in the child.

In the first run, the *date*(1) command is executed in the child, and the **posix_spawn**() call employs no file actions or attributes objects.

```
$ ./a.out date
PID of child: 7634
Tue Feb  1 19:47:50 CEST 2011
Child status: exited, status=0
```

In the next run, the *-c* command-line option is used to create a file actions object that closes standard output in the child. Consequently, *date*(1) fails when trying to perform output and exits with a status of 1.

```
$ ./a.out -c date
PID of child: 7636
date: write error: Bad file descriptor
Child status: exited, status=1
```

In the next run, the *-s* command-line option is used to create an attributes object that specifies that all (blockable) signals in the child should be blocked. Consequently, trying to kill child with the default signal sent by *kill*(1) (i.e., **SIGTERM**) fails, because that signal is blocked. Therefore, to kill the child, **SIGKILL** is necessary (**SIGKILL** can't be blocked).

```
$ ./a.out -s sleep 60 &
[1] 7637
$ PID of child: 7638

$ kill 7638
$ kill -KILL 7638
$ Child status: killed by signal 9
```

```
[1]+  Done                    ./a.out -s sleep 60
```

When we try to execute a nonexistent command in the child, the *exec*(3) fails and the child exits with a status of 127.

```
$ ./a.out xxxxx
PID of child: 10190
Child status: exited, status=127
```

NAME

pow, powf, powl − power functions

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double pow(double x, double y);
float powf(float x, float y);
long double powl(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

powf(), **powl**():

```
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
    || /* Since glibc 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

DESCRIPTION

These functions return the value of *x* raised to the power of *y*.

RETURN VALUE

On success, these functions return the value of *x* to the power of *y*.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the mathematically correct sign.

If result underflows, and is not representable, a range error occurs, and 0.0 with the appropriate sign is returned.

If *x* is +0 or −0, and *y* is an odd integer less than 0, a pole error occurs and **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, is returned, with the same sign as *x*.

If *x* is +0 or −0, and *y* is less than 0 and not an odd integer, a pole error occurs and +**HUGE_VAL**, +**HUGE_VALF**, or +**HUGE_VALL**, is returned.

If *x* is +0 (−0), and *y* is an odd integer greater than 0, the result is +0 (−0).

If *x* is 0, and *y* greater than 0 and not an odd integer, the result is +0.

If *x* is −1, and *y* is positive infinity or negative infinity, the result is 1.0.

If *x* is +1, the result is 1.0 (even if *y* is a NaN).

If *y* is 0, the result is 1.0 (even if *x* is a NaN).

If *x* is a finite value less than 0, and *y* is a finite noninteger, a domain error occurs, and a NaN is returned.

If the absolute value of *x* is less than 1, and *y* is negative infinity, the result is positive infinity.

If the absolute value of *x* is greater than 1, and *y* is negative infinity, the result is +0.

If the absolute value of *x* is less than 1, and *y* is positive infinity, the result is +0.

If the absolute value of *x* is greater than 1, and *y* is positive infinity, the result is positive infinity.

If *x* is negative infinity, and *y* is an odd integer less than 0, the result is −0.

If *x* is negative infinity, and *y* less than 0 and not an odd integer, the result is +0.

If *x* is negative infinity, and *y* is an odd integer greater than 0, the result is negative infinity.

If *x* is negative infinity, and *y* greater than 0 and not an odd integer, the result is positive infinity.

If *x* is positive infinity, and *y* less than 0, the result is +0.

If *x* is positive infinity, and *y* greater than 0, the result is positive infinity.

Except as specified above, if *x* or *y* is a NaN, the result is a NaN.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is negative, and *y* is a finite noninteger
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

Pole error: *x* is zero, and *y* is negative
: *errno* is set to **ERANGE** (but see BUGS). A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

Range error: the result overflows
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error: the result underflows
: *errno* is set to **ERANGE**. An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pow(), **powf**(), **powl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

BUGS

Historical bugs (now fixed)

Before glibc 2.28, on some architectures (e.g., x86-64) **pow**() may be more than 10,000 times slower for some inputs than for other nearby inputs. This affects only **pow**(), and not **powf**() nor **powl**(). This problem was fixed in glibc 2.28.

A number of bugs in the glibc implementation of **pow**() were fixed in glibc 2.16.

In glibc 2.9 and earlier, when a pole error occurs, *errno* is set to **EDOM** instead of the POSIX-mandated **ERANGE**. Since glibc 2.10, glibc does the right thing.

In glibc 2.3.2 and earlier, when an overflow or underflow error occurs, glibc's **pow**() generates a bogus invalid floating-point exception (**FE_INVALID**) in addition to the overflow or underflow exception.

NAME

pow10, pow10f, pow10l − base-10 power functions

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <math.h>

double pow10(double x);
float pow10f(float x);
long double pow10l(long double x);
```

DESCRIPTION

These functions return the value of 10 raised to the power *x*.

Note well: These functions perform exactly the same task as the functions described in *exp10*(3), with the difference that the latter functions are now standardized in TS 18661-4:2015. Those latter functions should be used in preference to the functions described in this page.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

powerof2 − test if a value is a power of 2

LIBRARY

Standard C library (*libc*)

SYNOPSIS

#include <sys/param.h>

int powerof2(*x***);**

DESCRIPTION

This macro returns true if *x* is a power of 2, and false otherwise.

0 is considered a power of 2. This can make sense considering wrapping of unsigned integers, and has interesting properties.

RETURN VALUE

True or false, if *x* is a power of 2 or not, respectively.

STANDARDS

BSD.

CAVEATS

The arguments may be evaluated more than once.

Because this macro is implemented using bitwise operations, some negative values can invoke undefined behavior. For example, the following invokes undefined behavior: *powerof2(INT_MIN);* . Call it only with unsigned types to be safe.

NAME

__ppc_get_timebase, __ppc_get_timebase_freq − get the current value of the Time Base Register on Power architecture and its frequency.

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/platform/ppc.h>

uint64_t __ppc_get_timebase(void);
uint64_t __ppc_get_timebase_freq(void);

DESCRIPTION

__ppc_get_timebase() reads the current value of the Time Base Register and returns its value, while **__ppc_get_timebase_freq**() returns the frequency in which the Time Base Register is updated.

The Time Base Register is a 64-bit register provided by Power Architecture processors. It stores a monotonically incremented value that is updated at a system-dependent frequency that may be different from the processor frequency.

RETURN VALUE

__ppc_get_timebase() returns a 64-bit unsigned integer that represents the current value of the Time Base Register.

__ppc_get_timebase_freq() returns a 64-bit unsigned integer that represents the frequency at which the Time Base Register is updated.

STANDARDS

GNU.

HISTORY

__ppc_get_timebase()
: glibc 2.16.

__ppc_get_timebase_freq()
: glibc 2.17.

EXAMPLES

The following program will calculate the time, in microseconds, spent between two calls to **__ppc_get_timebase**().

Program source

```
#include <inttypes.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/platform/ppc.h>

/* Maximum value of the Time Base Register: 2^60 − 1.
   Source: POWER ISA.  */
#define MAX_TB 0xFFFFFFFFFFFFFFF

int
main(void)
{
    uint64_t tb1, tb2, diff;
    uint64_t freq;

    freq = __ppc_get_timebase_freq();
    printf("Time Base frequency = %"PRIu64" Hz\n", freq);

    tb1 = __ppc_get_timebase();

    // Do some stuff...
```

```
        tb2 = __ppc_get_timebase();

        if (tb2 > tb1) {
            diff = tb2 - tb1;
        } else {
            /* Treat Time Base Register overflow.  */
            diff = (MAX_TB - tb2) + tb1;
        }

        printf("Elapsed time  = %1.2f usecs\n",
               (double) diff * 1000000 / freq);

        exit(EXIT_SUCCESS);
    }
```

Programmer's Manual"

NAME

__ppc_set_ppr_med, __ppc_set_ppr_very_low, __ppc_set_ppr_low, __ppc_set_ppr_med_low, __ppc_set_ppr_med_high − Set the Program Priority Register

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/platform/ppc.h>

void __ppc_set_ppr_med(void);
void __ppc_set_ppr_very_low(void);
void __ppc_set_ppr_low(void);
void __ppc_set_ppr_med_low(void);
void __ppc_set_ppr_med_high(void);

DESCRIPTION

These functions provide access to the *Program Priority Register* (PPR) on the Power architecture.

The PPR is a 64-bit register that controls the program's priority. By adjusting the PPR value the programmer may improve system throughput by causing system resources to be used more efficiently, especially in contention situations. The available unprivileged states are covered by the following functions:

__ppc_set_ppr_med()
: sets the Program Priority Register value to *medium* (default).

__ppc_set_ppr_very_low()
: sets the Program Priority Register value to *very low*.

__ppc_set_ppr_low()
: sets the Program Priority Register value to *low*.

__ppc_set_ppr_med_low()
: sets the Program Priority Register value to *medium low*.

The privileged state *medium high* may also be set during certain time intervals by problem-state (unprivileged) programs, with the following function:

__ppc_set_ppr_med_high()
: sets the Program Priority to *medium high*.

If the program priority is medium high when the time interval expires or if an attempt is made to set the priority to medium high when it is not allowed, the priority is set to medium.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
__ppc_set_ppr_med(), **__ppc_set_ppr_very_low**(), **__ppc_set_ppr_low**(), **__ppc_set_ppr_med_low**(), **__ppc_set_ppr_med_high**()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

__ppc_set_ppr_med()
__ppc_set_ppr_low()
__ppc_set_ppr_med_low()
: glibc 2.18.

__ppc_set_ppr_very_low()
__ppc_set_ppr_med_high()
: glibc 2.23.

NOTES

The functions **__ppc_set_ppr_very_low**() and **__ppc_set_ppr_med_high**() will be defined by <*sys/platform/ppc.h*> if **_ARCH_PWR8** is defined. Availability of these functions can be tested using **#ifdef _ARCH_PWR8**.

SEE ALSO

__ppc_yield(3)

Power ISA, Book II - Section 3.1 (Program Priority Registers)

NAME

__ppc_yield, __ppc_mdoio, __ppc_mdoom − Hint the processor to release shared resources

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/platform/ppc.h>

void __ppc_yield(void);
void __ppc_mdoio(void);
void __ppc_mdoom(void);

DESCRIPTION

These functions provide hints about the usage of resources that are shared with other processors on the Power architecture. They can be used, for example, if a program waiting on a lock intends to divert the shared resources to be used by other processors.

__ppc_yield() provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released for use by other processors.

__ppc_mdoio() provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released until all outstanding storage accesses to caching-inhibited storage have been completed.

__ppc_mdoom() provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released until all outstanding storage accesses to cacheable storage for which the data is not in the cache have been completed.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

printf, fprintf, dprintf, sprintf, snprintf, vprintf, vfprintf, vdprintf, vsprintf, vsnprintf − formatted output conversion

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int printf(const char *restrict format, ...);
int fprintf(FILE *restrict stream,
        const char *restrict format, ...);
int dprintf(int fd,
        const char *restrict format, ...);
int sprintf(char *restrict str,
        const char *restrict format, ...);
int snprintf(char str[restrict .size], size_t size,
        const char *restrict format, ...);

int vprintf(const char *restrict format, va_list ap);
int vfprintf(FILE *restrict stream,
        const char *restrict format, va_list ap);
int vdprintf(int fd,
        const char *restrict format, va_list ap);
int vsprintf(char *restrict str,
        const char *restrict format, va_list ap);
int vsnprintf(char str[restrict .size], size_t size,
        const char *restrict format, va_list ap);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

snprintf(), **vsnprintf**():
  _XOPEN_SOURCE >= 500 || _ISOC99_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE

dprintf(), **vdprintf**():
  Since glibc 2.10:
    _POSIX_C_SOURCE >= 200809L
  Before glibc 2.10:
    _GNU_SOURCE

DESCRIPTION

The functions in the **printf**() family produce output according to a *format* as described below. The functions **printf**() and **vprintf**() write output to *stdout*, the standard output stream; **fprintf**() and **vfprintf**() write output to the given output *stream*; **sprintf**(), **snprintf**(), **vsprintf**(), and **vsnprintf**() write to the character string *str*.

The function **dprintf**() is the same as **fprintf**() except that it outputs to a file descriptor, *fd*, instead of to a *stdio*(3) stream.

The functions **snprintf**() and **vsnprintf**() write at most *size* bytes (including the terminating null byte ('\0')) to *str*.

The functions **vprintf**(), **vfprintf**(), **vdprintf**(), **vsprintf**(), **vsnprintf**() are equivalent to the functions **printf**(), **fprintf**(), **dprintf**(), **sprintf**(), **snprintf**(), respectively, except that they are called with a *va_list* instead of a variable number of arguments. These functions do not call the *va_end* macro. Because they invoke the *va_arg* macro, the value of *ap* is undefined after the call. See *stdarg*(3).

All of these functions write the output under the control of a *format* string that specifies how subsequent arguments (or arguments accessed via the variable-length argument facilities of *stdarg*(3)) are converted for output.

C99 and POSIX.1-2001 specify that the results are undefined if a call to **sprintf**(), **snprintf**(), **vsprintf**(), or **vsnprintf**() would cause copying to take place between objects that overlap (e.g., if the target string array and one of the supplied input arguments refer to the same buffer). See CAVEATS.

Format of the format string

The format string is a character string, beginning and ending in its initial shift state, if any. The format string is composed of zero or more directives: ordinary characters (not **%**), which are copied unchanged to the output stream; and conversion specifications, each of which results in fetching zero or more subsequent arguments. Each conversion specification is introduced by the character **%**, and ends with a *conversion specifier*. In between there may be (in this order) zero or more *flags*, an optional minimum *field width*, an optional *precision* and an optional *length modifier*.

The overall syntax of a conversion specification is:

%[$][flags][width][.precision][length modifier]conversion

The arguments must correspond properly (after type promotion) with the conversion specifier. By default, the arguments are used in the order given, where each '*' (see *Field width* and *Precision* below) and each conversion specifier asks for the next argument (and it is an error if insufficiently many arguments are given). One can also specify explicitly which argument is taken, at each place where an argument is required, by writing "%m$" instead of '%' and "*m$" instead of '*', where the decimal integer *m* denotes the position in the argument list of the desired argument, indexed starting from 1. Thus,

```
printf("%*d", width, num);
```

and

```
printf("%2$*1$d", width, num);
```

are equivalent. The second style allows repeated references to the same argument. The C99 standard does not include the style using '$', which comes from the Single UNIX Specification. If the style using '$' is used, it must be used throughout for all conversions taking an argument and all width and precision arguments, but it may be mixed with "%%" formats, which do not consume an argument. There may be no gaps in the numbers of arguments specified using '$'; for example, if arguments 1 and 3 are specified, argument 2 must also be specified somewhere in the format string.

For some numeric conversions a radix character ("decimal point") or thousands' grouping character is used. The actual character used depends on the **LC_NUMERIC** part of the locale. (See *setlocale*(3).) The POSIX locale uses '.' as radix character, and does not have a grouping character. Thus,

```
printf("%'.2f", 1234567.89);
```

results in "1234567.89" in the POSIX locale, in "1234567,89" in the nl_NL locale, and in "1.234.567,89" in the da_DK locale.

Flag characters

The character % is followed by zero or more of the following flags:

The value should be converted to an "alternate form". For **o** conversions, the first character of the output string is made zero (by prefixing a 0 if it was not zero already). For **x** and **X** conversions, a nonzero result has the string "0x" (or "0X" for **X** conversions) prepended to it. For **a**, **A**, **e**, **E**, **f**, **F**, **g**, and **G** conversions, the result will always contain a decimal point, even if no digits follow it (normally, a decimal point appears in the results of those conversions only if a digit follows). For **g** and **G** conversions, trailing zeros are not removed from the result as they would otherwise be. For **m**, if *errno* contains a valid error code, the output of *strerrorname_np(errno)* is printed; otherwise, the value stored in *errno* is printed as a decimal number. For other conversions, the result is undefined.

0 The value should be zero padded. For **d**, **i**, **o**, **u**, **x**, **X**, **a**, **A**, **e**, **E**, **f**, **F**, **g**, and **G** conversions, the converted value is padded on the left with zeros rather than blanks. If the **0** and − flags both appear, the **0** flag is ignored. If a precision is given with an integer conversion (**d**, **i**, **o**, **u**, **x**, and **X**), the **0** flag is ignored. For other conversions, the behavior is undefined.

− The converted value is to be left adjusted on the field boundary. (The default is right justification.) The converted value is padded on the right with blanks, rather than on the left with blanks or zeros. A − overrides a **0** if both are given.

' ' (a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.

+ A sign (+ or −) should always be placed before a number produced by a signed conversion. By default, a sign is used only for negative numbers. A **+** overrides a space if both are used.

The five flag characters above are defined in the C99 standard. The Single UNIX Specification specifies one further flag character.

' For decimal conversion (**i**, **d**, **u**, **f**, **F**, **g**, **G**) the output is to be grouped with thousands' grouping characters if the locale information indicates any. (See *setlocale*(3).) Note that many versions of *gcc*(1) cannot parse this option and will issue a warning. (SUSv2 did not include *%'F*, but SUSv3 added it.) Note also that the default locale of a C program is "C" whose locale information indicates no thousands' grouping character. Therefore, without a prior call to *setlocale*(3), no thousands' grouping characters will be printed.

glibc 2.2 adds one further flag character.

I For decimal integer conversion (**i**, **d**, **u**) the output uses the locale's alternative output digits, if any. For example, since glibc 2.2.3 this will give Arabic-Indic digits in the Persian ("fa_IR") locale.

Field width

An optional decimal digit string (with nonzero first digit) specifying a minimum field width. If the converted value has fewer characters than the field width, it will be padded with spaces on the left (or right, if the left-adjustment flag has been given). Instead of a decimal digit string one may write "*" or "*m$" (for some decimal integer *m*) to specify that the field width is given in the next argument, or in the *m*-th argument, respectively, which must be of type *int*. A negative field width is taken as a '−' flag followed by a positive field width. In no case does a nonexistent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is expanded to contain the conversion result.

Precision

An optional precision, in the form of a period ('.') followed by an optional decimal digit string. Instead of a decimal digit string one may write "*" or "*m$" (for some decimal integer *m*) to specify that the precision is given in the next argument, or in the *m*-th argument, respectively, which must be of type *int*. If the precision is given as just '.', the precision is taken to be zero. A negative precision is taken as if the precision were omitted. This gives the minimum number of digits to appear for **d**, **i**, **o**, **u**, **x**, and **X** conversions, the number of digits to appear after the radix character for **a**, **A**, **e**, **E**, **f**, and **F** conversions, the maximum number of significant digits for **g** and **G** conversions, or the maximum number of characters to be printed from a string for **s** and **S** conversions.

Length modifier

Here, "integer conversion" stands for **d**, **i**, **o**, **u**, **x**, or **X** conversion.

hh A following integer conversion corresponds to a *signed char* or *unsigned char* argument, or a following **n** conversion corresponds to a pointer to a *signed char* argument.

h A following integer conversion corresponds to a *short* or *unsigned short* argument, or a following **n** conversion corresponds to a pointer to a *short* argument.

l (ell) A following integer conversion corresponds to a *long* or *unsigned long* argument, or a following **n** conversion corresponds to a pointer to a *long* argument, or a following **c** conversion corresponds to a *wint_t* argument, or a following **s** conversion corresponds to a pointer to *wchar_t* argument. On a following **a**, **A**, **e**, **E**, **f**, **F**, **g**, or **G** conversion, this length modifier is ignored (C99; not in SUSv2).

ll (ell-ell). A following integer conversion corresponds to a *long long* or *unsigned long long* argument, or a following **n** conversion corresponds to a pointer to a *long long* argument.

q A synonym for **ll**. This is a nonstandard extension, derived from BSD; avoid its use in new code.

L A following **a**, **A**, **e**, **E**, **f**, **F**, **g**, or **G** conversion corresponds to a *long double* argument. (C99 allows %LF, but SUSv2 does not.)

j A following integer conversion corresponds to an *intmax_t* or *uintmax_t* argument, or a following **n** conversion corresponds to a pointer to an *intmax_t* argument.

z A following integer conversion corresponds to a *size_t* or *ssize_t* argument, or a following **n** conversion corresponds to a pointer to a *size_t* argument.

Z A nonstandard synonym for **z** that predates the appearance of **z**. Do not use in new code.

t A following integer conversion corresponds to a *ptrdiff_t* argument, or a following **n** conversion corresponds to a pointer to a *ptrdiff_t* argument.

SUSv3 specifies all of the above, except for those modifiers explicitly noted as being nonstandard extensions. SUSv2 specified only the length modifiers **h** (in **hd**, **hi**, **ho**, **hx**, **hX**, **hn**) and **l** (in **ld**, **li**, **lo**, **lx**, **lX**, **ln**, **lc**, **ls**) and **L** (in **Le**, **LE**, **Lf**, **Lg**, **LG**).

As a nonstandard extension, the GNU implementations treats **ll** and **L** as synonyms, so that one can, for example, write **llg** (as a synonym for the standards-compliant **Lg**) and **Ld** (as a synonym for the standards compliant **lld**). Such usage is nonportable.

Conversion specifiers

A character that specifies the type of conversion to be applied. The conversion specifiers and their meanings are:

d, **i** The *int* argument is converted to signed decimal notation. The precision, if any, gives the minimum number of digits that must appear; if the converted value requires fewer digits, it is padded on the left with zeros. The default precision is 1. When 0 is printed with an explicit precision 0, the output is empty.

o, **u**, **x**, **X**

The *unsigned int* argument is converted to unsigned octal (**o**), unsigned decimal (**u**), or unsigned hexadecimal (**x** and **X**) notation. The letters **abcdef** are used for **x** conversions; the letters **ABCDEF** are used for **X** conversions. The precision, if any, gives the minimum number of digits that must appear; if the converted value requires fewer digits, it is padded on the left with zeros. The default precision is 1. When 0 is printed with an explicit precision 0, the output is empty.

e, **E** The *double* argument is rounded and converted in the style [−]d**.**ddd**e**±dd where there is one digit (which is nonzero if the argument is nonzero) before the decimal-point character and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is zero, no decimal-point character appears. An **E** conversion uses the letter **E** (rather than **e**) to introduce the exponent. The exponent always contains at least two digits; if the value is zero, the exponent is 00.

f, **F** The *double* argument is rounded and converted to decimal notation in the style [−]ddd**.**ddd, where the number of digits after the decimal-point character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is explicitly zero, no decimal-point character appears. If a decimal point appears, at least one digit appears before it.

(SUSv2 does not know about **F** and says that character string representations for infinity and NaN may be made available. SUSv3 adds a specification for **F**. The C99 standard specifies "[−]inf" or "[−]infinity" for infinity, and a string starting with "nan" for NaN, in the case of **f** conversion, and "[−]INF" or "[−]INFINITY" or "NAN" in the case of **F** conversion.)

g, **G** The *double* argument is converted in style **f** or **e** (or **F** or **E** for **G** conversions). The precision specifies the number of significant digits. If the precision is missing, 6 digits are given; if the precision is zero, it is treated as 1. Style **e** is used if the exponent from its conversion is less than −4 or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result; a decimal point appears only if it is followed by at least one digit.

a, **A** (C99; not in SUSv2, but added in SUSv3) For **a** conversion, the *double* argument is converted to hexadecimal notation (using the letters abcdef) in the style [−]**0x**h**.**hhhh**p**±d; for **A** conversion the prefix **0X**, the letters ABCDEF, and the exponent separator **P** is used. There is one hexadecimal digit before the decimal point, and the number of digits after it is equal to the precision. The default precision suffices for an exact representation of the value if an exact representation in base 2 exists and otherwise is sufficiently large to distinguish values of type *double*. The digit before the decimal point is unspecified for nonnormalized numbers, and nonzero but otherwise unspecified for normalized numbers. The exponent always contains at least one digit; if the value is zero, the exponent is 0.

c If no **l** modifier is present, the *int* argument is converted to an *unsigned char*, and the resulting character is written. If an **l** modifier is present, the *wint_t* (wide character) argument is converted to a multibyte sequence by a call to the *wcrtomb*(3) function, with a conversion state starting in the initial state, and the resulting multibyte string is written.

s If no **l** modifier is present: the *const char* * argument is expected to be a pointer to an array of character type (pointer to a string). Characters from the array are written up to (but not including) a terminating null byte ('\0'); if a precision is specified, no more than the number specified are written. If a precision is given, no null byte need be present; if the precision is not specified, or is greater than the size of the array, the array must contain a terminating null byte.

If an **l** modifier is present: the *const wchar_t* * argument is expected to be a pointer to an array of wide characters. Wide characters from the array are converted to multibyte characters (each by a call to the *wcrtomb*(3) function, with a conversion state starting in the initial state before the first wide character), up to and including a terminating null wide character. The resulting multibyte characters are written up to (but not including) the terminating null byte. If a precision is specified, no more bytes than the number specified are written, but no partial multibyte characters are written. Note that the precision determines the number of *bytes* written, not the number of *wide characters* or *screen positions*. The array must contain a terminating null wide character, unless a precision is given and it is so small that the number of bytes written exceeds it before the end of the array is reached.

C (Not in C99 or C11, but in SUSv2, SUSv3, and SUSv4.) Synonym for **lc**. Don't use.

S (Not in C99 or C11, but in SUSv2, SUSv3, and SUSv4.) Synonym for **ls**. Don't use.

p The *void* * pointer argument is printed in hexadecimal (as if by **%#x** or **%#lx**).

n The number of characters written so far is stored into the integer pointed to by the corresponding argument. That argument shall be an *int* *, or variant whose size matches the (optionally) supplied integer length modifier. No argument is converted. (This specifier is not supported by the bionic C library.) The behavior is undefined if the conversion specification includes any flags, a field width, or a precision.

m (glibc extension; supported by uClibc and musl.) Print output of *strerror(errno)* (or *strerrorname_np(errno)* in the alternate form). No argument is required.

% A '%' is written. No argument is converted. The complete conversion specification is '%%'.

RETURN VALUE

Upon successful return, these functions return the number of bytes printed (excluding the null byte used to end output to strings).

The functions **snprintf**() and **vsnprintf**() do not write more than *size* bytes (including the terminating null byte ('\0')). If the output was truncated due to this limit, then the return value is the number of characters (excluding the terminating null byte) which would have been written to the final string if enough space had been available. Thus, a return value of *size* or more means that the output was truncated. (See also below under CAVEATS.)

If an output error is encountered, a negative value is returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
printf(), **fprintf**(), **sprintf**(), **snprintf**(), **vprintf**(), **vfprintf**(), **vsprintf**(), **vsnprintf**()	Thread safety	MT-Safe locale

STANDARDS

fprintf()
printf()
sprintf()
vprintf()
vfprintf()
vsprintf()

snprintf()
vsnprintf()
C11, POSIX.1-2008.

dprintf()
vdprintf()
GNU, POSIX.1-2008.

HISTORY

fprintf()
printf()
sprintf()
vprintf()
vfprintf()
vsprintf()
C89, POSIX.1-2001.

snprintf()
vsnprintf()
SUSv2, C99, POSIX.1-2001.

Concerning the return value of **snprintf**(), SUSv2 and C99 contradict each other: when **snprintf**() is called with *size*=0 then SUSv2 stipulates an unspecified return value less than 1, while C99 allows *str* to be NULL in this case, and gives the return value (as always) as the number of characters that would have been written in case the output string has been large enough. POSIX.1-2001 and later align their specification of **snprintf**() with C99.

dprintf()
vdprintf()
GNU, POSIX.1-2008.

glibc 2.1 adds length modifiers **hh**, **j**, **t**, and **z** and conversion characters **a** and **A**.

glibc 2.2 adds the conversion character **F** with C99 semantics, and the flag character **I**.

glibc 2.35 gives a meaning to the alternate form (**#**) of the **m** conversion specifier, that is *%#m*.

CAVEATS

Some programs imprudently rely on code such as the following

```
sprintf(buf, "%s some further text", buf);
```

to append text to *buf*. However, the standards explicitly note that the results are undefined if source and destination buffers overlap when calling **sprintf**(), **snprintf**(), **vsprintf**(), and **vsnprintf**(). Depending on the version of *gcc*(1) used, and the compiler options employed, calls such as the above will **not** produce the expected results.

The glibc implementation of the functions **snprintf**() and **vsnprintf**() conforms to the C99 standard, that is, behaves as described above, since glibc 2.1. Until glibc 2.0.6, they would return −1 when the output was truncated.

BUGS

Because **sprintf**() and **vsprintf**() assume an arbitrarily long string, callers must be careful not to overflow the actual space; this is often impossible to assure. Note that the length of the strings produced is locale-dependent and difficult to predict. Use **snprintf**() and **vsnprintf**() instead (or *asprintf*(3) and *vasprintf*(3)).

Code such as **printf(** *foo***);** often indicates a bug, since *foo* may contain a % character. If *foo* comes from untrusted user input, it may contain **%n**, causing the **printf**() call to write to memory and creating a security hole.

EXAMPLES

To print *Pi* to five decimal places:

```
#include <math.h>
#include <stdio.h>
fprintf(stdout, "pi = %.5f\n", 4 * atan(1.0));
```

To print a date and time in the form "Sunday, July 3, 10:02", where *weekday* and *month* are pointers to

strings:

```
#include <stdio.h>
fprintf(stdout, "%s, %s %d, %.2d:%.2d\n",
        weekday, month, day, hour, min);
```

Many countries use the day-month-year order. Hence, an internationalized version must be able to print the arguments in an order specified by the format:

```
#include <stdio.h>
fprintf(stdout, format,
        weekday, month, day, hour, min);
```

where *format* depends on locale, and may permute the arguments. With the value:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

one might obtain "Sonntag, 3. Juli, 10:02".

To allocate a sufficiently large string and print into it (code correct for both glibc 2.0 and glibc 2.1):

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>

char *
make_message(const char *fmt, ...)
{
    int n = 0;
    size_t size = 0;
    char *p = NULL;
    va_list ap;

    /* Determine required size. */

    va_start(ap, fmt);
    n = vsnprintf(p, size, fmt, ap);
    va_end(ap);

    if (n < 0)
        return NULL;

    size = (size_t) n + 1;      /* One extra byte for '\0' */
    p = malloc(size);
    if (p == NULL)
        return NULL;

    va_start(ap, fmt);
    n = vsnprintf(p, size, fmt, ap);
    va_end(ap);

    if (n < 0) {
        free(p);
        return NULL;
    }

    return p;
}
```

If truncation occurs in glibc versions prior to glibc 2.0.6, this is treated as an error instead of being handled gracefully.

NAME

profil − execution time profile

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

int profil(unsigned short *buf, size_t bufsiz,
           size_t offset, unsigned int scale);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

profil():
Since glibc 2.21:
_DEFAULT_SOURCE
In glibc 2.19 and 2.20:
_DEFAULT_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)
Up to and including glibc 2.19:
_BSD_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)

DESCRIPTION

This routine provides a means to find out in what areas your program spends most of its time. The argument *buf* points to *bufsiz* bytes of core. Every virtual 10 milliseconds, the user's program counter (PC) is examined: *offset* is subtracted and the result is multiplied by *scale* and divided by 65536. If the resulting value is less than *bufsiz*, then the corresponding entry in *buf* is incremented. If *buf* is NULL, profiling is disabled.

RETURN VALUE

Zero is always returned.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
profil()	Thread safety	MT-Unsafe

STANDARDS

None.

HISTORY

Similar to a call in SVr4.

BUGS

profil() cannot be used on a program that also uses **ITIMER_PROF** interval timers (see *setitimer*(2)).

True kernel profiling provides more accurate results.

SEE ALSO

gprof (1), *sprof*(1), *setitimer*(2), *sigaction*(2), *signal*(2)

NAME

program_invocation_name, program_invocation_short_name − obtain name used to invoke calling program

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <errno.h>

extern char *program_invocation_name;
extern char *program_invocation_short_name;
```

DESCRIPTION

program_invocation_name contains the name that was used to invoke the calling program. This is the same as the value of *argv[0]* in *main*(), with the difference that the scope of *program_invocation_name* is global.

program_invocation_short_name contains the basename component of name that was used to invoke the calling program. That is, it is the same value as *program_invocation_name*, with all text up to and including the final slash (/), if any, removed.

These variables are automatically initialized by the glibc run-time startup code.

VERSIONS

The Linux-specific */proc/*pid*/cmdline* file provides access to similar information.

STANDARDS

GNU.

proc(5)

NAME

psignal, psiginfo − print signal description

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <signal.h>

void psignal(int *sig***, const char ****s***);**
void psiginfo(const siginfo_t ****pinfo*, const char ****s***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

psignal():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

psiginfo():
_POSIX_C_SOURCE >= 200809L

DESCRIPTION

The **psignal**() function displays a message on *stderr* consisting of the string *s*, a colon, a space, a string describing the signal number *sig*, and a trailing newline. If the string *s* is NULL or empty, the colon and space are omitted. If *sig* is invalid, the message displayed will indicate an unknown signal.

The **psiginfo**() function is like **psignal**(), except that it displays information about the signal described by *pinfo*, which should point to a valid *siginfo_t* structure. As well as the signal description, **psiginfo**() displays information about the origin of the signal, and other information relevant to the signal (e.g., the relevant memory address for hardware-generated signals, the child process ID for **SIGCHLD**, and the user ID and process ID of the sender, for signals set using *kill*(2) or *sigqueue*(3)).

RETURN VALUE

The **psignal**() and **psiginfo**() functions return no value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
psignal(), **psiginfo**()	Thread safety	MT-Safe locale

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.10. POSIX.1-2008, 4.3BSD.

BUGS

Up to glibc 2.12, **psiginfo**() had the following bugs:

- In some circumstances, a trailing newline is not printed.
- Additional details are not displayed for real-time signals.

sigaction(2), *perror*(3), *strsignal*(3), *signal*(7)

NAME

pthread_atfork − register fork handlers

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_atfork(void (**prepare***)(void), void (****parent***)(void),**
void (**child***)(void));**

DESCRIPTION

The **pthread_atfork**() function registers fork handlers that are to be executed when *fork*(2) is called by any thread in a process. The handlers are executed in the context of the thread that calls *fork*(2).

Three kinds of handler can be registered:

- *prepare* specifies a handler that is executed in the parent process before *fork*(2) processing starts.
- *parent* specifies a handler that is executed in the parent process after *fork*(2) processing completes.
- *child* specifies a handler that is executed in the child process after *fork*(2) processing completes.

Any of the three arguments may be NULL if no handler is needed in the corresponding phase of *fork*(2) processing.

RETURN VALUE

On success, **pthread_atfork**() returns zero. On error, it returns an error number. **pthread_atfork**() may be called multiple times by a process to register additional handlers. The handlers for each phase are called in a specified order: the *prepare* handlers are called in reverse order of registration; the *parent* and *child* handlers are called in the order of registration.

ERRORS

ENOMEM
Could not allocate memory to record the fork handler list entry.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

When *fork*(2) is called in a multithreaded process, only the calling thread is duplicated in the child process. The original intention of **pthread_atfork**() was to allow the child process to be returned to a consistent state. For example, at the time of the call to *fork*(2), other threads may have locked mutexes that are visible in the user-space memory duplicated in the child. Such mutexes would never be unlocked, since the threads that placed the locks are not duplicated in the child. The intent of **pthread_atfork**() was to provide a mechanism whereby the application (or a library) could ensure that mutexes and other process and thread state would be restored to a consistent state. In practice, this task is generally too difficult to be practicable.

After a *fork*(2) in a multithreaded process returns in the child, the child should call only async-signal-safe functions (see *signal-safety*(7)) until such time as it calls *execve*(2) to execute a new program.

POSIX.1 specifies that **pthread_atfork**() shall not fail with the error **EINTR**.

SEE ALSO

fork(2), *atexit*(3), *pthreads*(7)

NAME

pthread_attr_init, pthread_attr_destroy − initialize and destroy thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_attr_init(pthread_attr_t *_attr_);
int pthread_attr_destroy(pthread_attr_t *_attr_);

DESCRIPTION

The **pthread_attr_init**() function initializes the thread attributes object pointed to by *attr* with default attribute values. After this call, individual attributes of the object can be set using various related functions (listed under SEE ALSO), and then the object can be used in one or more *pthread_create*(3) calls that create threads.

Calling **pthread_attr_init**() on a thread attributes object that has already been initialized results in undefined behavior.

When a thread attributes object is no longer required, it should be destroyed using the **pthread_attr_destroy**() function. Destroying a thread attributes object has no effect on threads that were created using that object.

Once a thread attributes object has been destroyed, it can be reinitialized using **pthread_attr_init**(). Any other use of a destroyed thread attributes object has undefined results.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

POSIX.1 documents an **ENOMEM** error for **pthread_attr_init**(); on Linux these functions always succeed (but portable and future-proof applications should nevertheless handle a possible error return).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_init(), **pthread_attr_destroy**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

The *pthread_attr_t* type should be treated as opaque: any access to the object other than via pthreads functions is nonportable and produces undefined results.

EXAMPLES

The program below optionally makes use of **pthread_attr_init**() and various related functions to initialize a thread attributes object that is used to create a single thread. Once created, the thread uses the *pthread_getattr_np*(3) function (a nonstandard GNU extension) to retrieve the thread's attributes, and then displays those attributes.

If the program is run with no command-line argument, then it passes NULL as the *attr* argument of *pthread_create*(3), so that the thread is created with default attributes. Running the program on Linux/x86-32 with the NPTL threading implementation, we see the following:

```
$ ulimit -s       # No stack limit ==> default stack size is 2 MB
unlimited
$ ./a.out
Thread attributes:
        Detach state        = PTHREAD_CREATE_JOINABLE
        Scope               = PTHREAD_SCOPE_SYSTEM
        Inherit scheduler   = PTHREAD_INHERIT_SCHED
        Scheduling policy   = SCHED_OTHER
```

```
        Scheduling priority = 0
        Guard size          = 4096 bytes
        Stack address       = 0x40196000
        Stack size          = 0x201000 bytes
```

When we supply a stack size as a command-line argument, the program initializes a thread attributes object, sets various attributes in that object, and passes a pointer to the object in the call to *pthread_create*(3). Running the program on Linux/x86-32 with the NPTL threading implementation, we see the following:

```
$ ./a.out 0x3000000
posix_memalign() allocated at 0x40197000
Thread attributes:
        Detach state        = PTHREAD_CREATE_DETACHED
        Scope               = PTHREAD_SCOPE_SYSTEM
        Inherit scheduler   = PTHREAD_EXPLICIT_SCHED
        Scheduling policy   = SCHED_OTHER
        Scheduling priority = 0
        Guard size          = 0 bytes
        Stack address       = 0x40197000
        Stack size          = 0x3000000 bytes
```

NAME

pthread_attr_setaffinity_np, pthread_attr_getaffinity_np − set/get CPU affinity attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_attr_setaffinity_np(pthread_attr_t *attr,
                size_t cpusetsize, const cpu_set_t *cpuset);
int pthread_attr_getaffinity_np(const pthread_attr_t *attr,
                size_t cpusetsize, cpu_set_t *cpuset);
```

DESCRIPTION

The **pthread_attr_setaffinity_np**() function sets the CPU affinity mask attribute of the thread attributes object referred to by *attr* to the value specified in *cpuset*. This attribute determines the CPU affinity mask of a thread created using the thread attributes object *attr*.

The **pthread_attr_getaffinity_np**() function returns the CPU affinity mask attribute of the thread attributes object referred to by *attr* in the buffer pointed to by *cpuset*.

The argument *cpusetsize* is the length (in bytes) of the buffer pointed to by *cpuset*. Typically, this argument would be specified as *sizeof(cpu_set_t)*.

For more details on CPU affinity masks, see *sched_setaffinity*(2). For a description of a set of macros that can be used to manipulate and inspect CPU sets, see *CPU_SET*(3).

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

EINVAL

(**pthread_attr_setaffinity_np**()) *cpuset* specified a CPU that was outside the set supported by the kernel. (The kernel configuration option **CONFIG_NR_CPUS** defines the range of the set supported by the kernel data type used to represent CPU sets.)

EINVAL

(**pthread_attr_getaffinity_np**()) A CPU in the affinity mask of the thread attributes object referred to by *attr* lies outside the range specified by *cpusetsize* (i.e., *cpuset*/*cpusetsize* is too small).

ENOMEM

(**pthread_attr_setaffinity_np**()) Could not allocate memory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setaffinity_np(), **pthread_attr_getaffinity_np**()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.3.4.

NOTES

In glibc 2.3.3 only, versions of these functions were provided that did not have a *cpusetsize* argument. Instead the CPU set size given to the underlying system calls was always *sizeof(cpu_set_t)*.

NAME

pthread_attr_setdetachstate, pthread_attr_getdetachstate − set/get detach state attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);
int pthread_attr_getdetachstate(const pthread_attr_t *attr,
                                int *detachstate);
```

DESCRIPTION

The **pthread_attr_setdetachstate**() function sets the detach state attribute of the thread attributes object referred to by *attr* to the value specified in *detachstate*. The detach state attribute determines whether a thread created using the thread attributes object *attr* will be created in a joinable or a detached state.

The following values may be specified in *detachstate*:

PTHREAD_CREATE_DETACHED
: Threads that are created using *attr* will be created in a detached state.

PTHREAD_CREATE_JOINABLE
: Threads that are created using *attr* will be created in a joinable state.

The default setting of the detach state attribute in a newly initialized thread attributes object is **PTHREAD_CREATE_JOINABLE**.

The **pthread_attr_getdetachstate**() returns the detach state attribute of the thread attributes object *attr* in the buffer pointed to by *detachstate*.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setdetachstate() can fail with the following error:

EINVAL
: An invalid value was specified in *detachstate*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setdetachstate(), **pthread_attr_getdetachstate**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

See *pthread_create*(3) for more details on detached and joinable threads.

A thread that is created in a joinable state should eventually either be joined using *pthread_join*(3) or detached using *pthread_detach*(3); see *pthread_create*(3).

It is an error to specify the thread ID of a thread that was created in a detached state in a later call to *pthread_detach*(3) or *pthread_join*(3).

EXAMPLES

See *pthread_attr_init*(3).

pthread_attr_init(3), *pthread_create*(3), *pthread_detach*(3), *pthread_join*(3), *pthreads*(7)

NAME

pthread_attr_setguardsize, pthread_attr_getguardsize − set/get guard size attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setguardsize(pthread_attr_t *attr, size_t guardsize);
int pthread_attr_getguardsize(const pthread_attr_t *restrict attr,
                              size_t *restrict guardsize);
```

DESCRIPTION

The **pthread_attr_setguardsize**() function sets the guard size attribute of the thread attributes object referred to by *attr* to the value specified in *guardsize*.

If *guardsize* is greater than 0, then for each new thread created using *attr* the system allocates an additional region of at least *guardsize* bytes at the end of the thread's stack to act as the guard area for the stack (but see BUGS).

If *guardsize* is 0, then new threads created with *attr* will not have a guard area.

The default guard size is the same as the system page size.

If the stack address attribute has been set in *attr* (using *pthread_attr_setstack*(3) or *pthread_attr_setstackaddr*(3)), meaning that the caller is allocating the thread's stack, then the guard size attribute is ignored (i.e., no guard area is created by the system): it is the application's responsibility to handle stack overflow (perhaps by using *mprotect*(2) to manually define a guard area at the end of the stack that it has allocated).

The **pthread_attr_getguardsize**() function returns the guard size attribute of the thread attributes object referred to by *attr* in the buffer pointed to by *guardsize*.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

POSIX.1 documents an **EINVAL** error if *attr* or *guardsize* is invalid. On Linux these functions always succeed (but portable and future-proof applications should nevertheless handle a possible error return).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setguardsize(), **pthread_attr_getguardsize**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

NOTES

A guard area consists of virtual memory pages that are protected to prevent read and write access. If a thread overflows its stack into the guard area, then, on most hard architectures, it receives a **SIGSEGV** signal, thus notifying it of the overflow. Guard areas start on page boundaries, and the guard size is internally rounded up to the system page size when creating a thread. (Nevertheless, **pthread_attr_getguardsize**() returns the guard size that was set by *pthread_attr_setguardsize*().)

Setting a guard size of 0 may be useful to save memory in an application that creates many threads and knows that stack overflow can never occur.

Choosing a guard size larger than the default size may be necessary for detecting stack overflows if a thread allocates large data structures on the stack.

BUGS

As at glibc 2.8, the NPTL threading implementation includes the guard area within the stack size allocation, rather than allocating extra space at the end of the stack, as POSIX.1 requires. (This can result

in an **EINVAL** error from *pthread_create*(3) if the guard size value is too large, leaving no space for the actual stack.)

The obsolete LinuxThreads implementation did the right thing, allocating extra space at the end of the stack for the guard area.

EXAMPLES

See *pthread_getattr_np*(3).

NAME

pthread_attr_setinheritsched, pthread_attr_getinheritsched − set/get inherit-scheduler attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setinheritsched(pthread_attr_t *attr,
                                 int inheritsched);
int pthread_attr_getinheritsched(const pthread_attr_t *restrict attr,
                                 int *restrict inheritsched);
```

DESCRIPTION

The **pthread_attr_setinheritsched**() function sets the inherit-scheduler attribute of the thread attributes object referred to by *attr* to the value specified in *inheritsched*. The inherit-scheduler attribute determines whether a thread created using the thread attributes object *attr* will inherit its scheduling attributes from the calling thread or whether it will take them from *attr*.

The following scheduling attributes are affected by the inherit-scheduler attribute: scheduling policy (**pthread_attr_setschedpolicy**(3)), scheduling priority (**pthread_attr_setschedparam**(3)), and contention scope (**pthread_attr_setscope**(3)).

The following values may be specified in *inheritsched*:

PTHREAD_INHERIT_SCHED
: Threads that are created using *attr* inherit scheduling attributes from the creating thread; the scheduling attributes in *attr* are ignored.

PTHREAD_EXPLICIT_SCHED
: Threads that are created using *attr* take their scheduling attributes from the values specified by the attributes object.

The default setting of the inherit-scheduler attribute in a newly initialized thread attributes object is **PTHREAD_INHERIT_SCHED**.

The **pthread_attr_getinheritsched**() returns the inherit-scheduler attribute of the thread attributes object *attr* in the buffer pointed to by *inheritsched*.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setinheritsched() can fail with the following error:

EINVAL
: Invalid value in *inheritsched*.

POSIX.1 also documents an optional **ENOTSUP** error ("attempt was made to set the attribute to an unsupported value") for **pthread_attr_setinheritsched**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setinheritsched(), **pthread_attr_getinheritsched**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.0. POSIX.1-2001.

BUGS

As at glibc 2.8, if a thread attributes object is initialized using *pthread_attr_init*(3), then the scheduling policy of the attributes object is set to **SCHED_OTHER** and the scheduling priority is set to 0. However, if the inherit-scheduler attribute is then set to **PTHREAD_EXPLICIT_SCHED**, then a thread created using the attribute object wrongly inherits its scheduling attributes from the creating thread.

This bug does not occur if either the scheduling policy or scheduling priority attribute is explicitly set in the thread attributes object before calling *pthread_create*(3).

EXAMPLES

See *pthread_setschedparam*(3).

SEE ALSO

pthread_attr_init(3), *pthread_attr_setschedparam*(3), *pthread_attr_setschedpolicy*(3), *pthread_attr_setscope*(3), *pthread_create*(3), *pthread_setschedparam*(3), *pthread_setschedprio*(3), *pthreads*(7), *sched*(7)

NAME

pthread_attr_setschedparam, pthread_attr_getschedparam − set/get scheduling parameter attributes in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setschedparam(pthread_attr_t *restrict attr,
                               const struct sched_param *restrict param);
int pthread_attr_getschedparam(const pthread_attr_t *restrict attr,
                               struct sched_param *restrict param);
```

DESCRIPTION

The **pthread_attr_setschedparam**() function sets the scheduling parameter attributes of the thread attributes object referred to by *attr* to the values specified in the buffer pointed to by *param*. These attributes determine the scheduling parameters of a thread created using the thread attributes object *attr*.

The **pthread_attr_getschedparam**() returns the scheduling parameter attributes of the thread attributes object *attr* in the buffer pointed to by *param*.

Scheduling parameters are maintained in the following structure:

```
struct sched_param {
    int sched_priority;     /* Scheduling priority */
};
```

As can be seen, only one scheduling parameter is supported. For details of the permitted ranges for scheduling priorities in each scheduling policy, see *sched*(7).

In order for the parameter setting made by **pthread_attr_setschedparam**() to have effect when calling *pthread_create*(3), the caller must use *pthread_attr_setinheritsched*(3) to set the inherit-scheduler attribute of the attributes object *attr* to **PTHREAD_EXPLICIT_SCHED**.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setschedparam() can fail with the following error:

EINVAL
The priority specified in *param* does not make sense for the current scheduling policy of *attr*.

POSIX.1 also documents an **ENOTSUP** error for **pthread_attr_setschedparam**(). This value is never returned on Linux (but portable and future-proof applications should nevertheless handle this error return value).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setschedparam(), **pthread_attr_getschedparam**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001. glibc 2.0.

NOTES

See *pthread_attr_setschedpolicy*(3) for a list of the thread scheduling policies supported on Linux.

EXAMPLES

See *pthread_setschedparam*(3).

SEE ALSO

sched_get_priority_min(2), *pthread_attr_init*(3), *pthread_attr_setinheritsched*(3), *pthread_attr_setschedpolicy*(3), *pthread_create*(3), *pthread_setschedparam*(3), *pthread_setschedprio*(3), *pthreads*(7), *sched*(7)

NAME

pthread_attr_setschedpolicy, pthread_attr_getschedpolicy − set/get scheduling policy attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setschedpolicy(pthread_attr_t *attr, int policy);
int pthread_attr_getschedpolicy(const pthread_attr_t *restrict attr,
                                int *restrict policy);
```

DESCRIPTION

The **pthread_attr_setschedpolicy**() function sets the scheduling policy attribute of the thread attributes object referred to by *attr* to the value specified in *policy*. This attribute determines the scheduling policy of a thread created using the thread attributes object *attr*.

The supported values for *policy* are **SCHED_FIFO**, **SCHED_RR**, and **SCHED_OTHER**, with the semantics described in *sched*(7).

The **pthread_attr_getschedpolicy**() returns the scheduling policy attribute of the thread attributes object *attr* in the buffer pointed to by *policy*.

In order for the policy setting made by **pthread_attr_setschedpolicy**() to have effect when calling *pthread_create*(3), the caller must use *pthread_attr_setinheritsched*(3) to set the inherit-scheduler attribute of the attributes object *attr* to **PTHREAD_EXPLICIT_SCHED**.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setschedpolicy() can fail with the following error:

EINVAL
: Invalid value in *policy*.

POSIX.1 also documents an optional **ENOTSUP** error ("attempt was made to set the attribute to an unsupported value") for **pthread_attr_setschedpolicy**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setschedpolicy(), **pthread_attr_getschedpolicy**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

EXAMPLES

See *pthread_setschedparam*(3).

SEE ALSO

pthread_attr_init(3), *pthread_attr_setinheritsched*(3), *pthread_attr_setschedparam*(3), *pthread_create*(3), *pthread_setschedparam*(3), *pthread_setschedprio*(3), *pthreads*(7), *sched*(7)

NAME

pthread_attr_setscope, pthread_attr_getscope − set/get contention scope attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setscope(pthread_attr_t *attr, int scope);
int pthread_attr_getscope(const pthread_attr_t *restrict attr,
                          int *restrict scope);
```

DESCRIPTION

The **pthread_attr_setscope**() function sets the contention scope attribute of the thread attributes object referred to by *attr* to the value specified in *scope*. The contention scope attribute defines the set of threads against which a thread competes for resources such as the CPU. POSIX.1 specifies two possible values for *scope*:

PTHREAD_SCOPE_SYSTEM
: The thread competes for resources with all other threads in all processes on the system that are in the same scheduling allocation domain (a group of one or more processors). **PTHREAD_SCOPE_SYSTEM** threads are scheduled relative to one another according to their scheduling policy and priority.

PTHREAD_SCOPE_PROCESS
: The thread competes for resources with all other threads in the same process that were also created with the **PTHREAD_SCOPE_PROCESS** contention scope. **PTHREAD_SCOPE_PROCESS** threads are scheduled relative to other threads in the process according to their scheduling policy and priority. POSIX.1 leaves it unspecified how these threads contend with other threads in other process on the system or with other threads in the same process that were created with the **PTHREAD_SCOPE_SYSTEM** contention scope.

POSIX.1 requires that an implementation support at least one of these contention scopes. Linux supports **PTHREAD_SCOPE_SYSTEM**, but not **PTHREAD_SCOPE_PROCESS**.

On systems that support multiple contention scopes, then, in order for the parameter setting made by **pthread_attr_setscope**() to have effect when calling *pthread_create*(3), the caller must use *pthread_attr_setinheritsched*(3) to set the inherit-scheduler attribute of the attributes object *attr* to **PTHREAD_EXPLICIT_SCHED**.

The **pthread_attr_getscope**() function returns the contention scope attribute of the thread attributes object referred to by *attr* in the buffer pointed to by *scope*.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setscope() can fail with the following errors:

EINVAL
: An invalid value was specified in *scope*.

ENOTSUP
: *scope* specified the value **PTHREAD_SCOPE_PROCESS**, which is not supported on Linux.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setscope(), **pthread_attr_getscope**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

The **PTHREAD_SCOPE_SYSTEM** contention scope typically indicates that a user-space thread is bound directly to a single kernel-scheduling entity. This is the case on Linux for the obsolete LinuxThreads implementation and the modern NPTL implementation, which are both 1:1 threading implementations.

POSIX.1 specifies that the default contention scope is implementation-defined.

pthread_attr_init(3), *pthread_attr_setaffinity_np*(3), *pthread_attr_setinheritsched*(3), *pthread_attr_setschedparam*(3), *pthread_attr_setschedpolicy*(3), *pthread_create*(3), *pthreads*(7)

NAME

pthread_attr_setsigmask_np, pthread_attr_getsigmask_np − set/get signal mask attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_attr_setsigmask_np(pthread_attr_t *attr,
                               const sigset_t *sigmask);
int pthread_attr_getsigmask_np(const pthread_attr_t *attr,
                               sigset_t *sigmask);
```

DESCRIPTION

The **pthread_attr_setsigmask_np**() function sets the signal mask attribute of the thread attributes object referred to by *attr* to the value specified in **sigmask*. If *sigmask* is specified as NULL, then any existing signal mask attribute in *attr* is unset.

The **pthread_attr_getsigmask_np**() function returns the signal mask attribute of the thread attributes object referred to by *attr* in the buffer pointed to by *sigmask*. If the signal mask attribute is currently unset, then this function returns the special value **PTHREAD_ATTR_NO_SIGMASK_NP** as its result.

RETURN VALUE

The **pthread_attr_setsigmask_np**() function returns 0 on success, or a nonzero error number on failure.

the **pthread_attr_getsigmask_np**() function returns either 0 or **PTHREAD_ATTR_NO_SIGMASK_NP**. When 0 is returned, the signal mask attribute is returned via *sigmask*. A return value of **PTHREAD_ATTR_NO_SIGMASK_NP** indicates that the signal mask attribute is not set in *attr*.

On error, these functions return a positive error number.

ERRORS

ENOMEM
(**pthread_attr_setsigmask_np**()) Could not allocate memory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setsigmask_np(), **pthread_attr_getsigmask_np**()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.32.

NOTES

The signal mask attribute determines the signal mask that will be assigned to a thread created using the thread attributes object *attr*. If this attribute is not set, then a thread created using *attr* will inherit a copy of the creating thread's signal mask.

For more details on signal masks, see *sigprocmask*(2). For a description of a set of macros that can be used to manipulate and inspect signal sets, see *sigsetops*(3).

In the absence of **pthread_attr_setsigmask_np**() it is possible to create a thread with a desired signal mask as follows:

- The creating thread uses *pthread_sigmask*(3) to save its current signal mask and set its mask to block all signals.
- The new thread is then created using **pthread_create**(); the new thread will inherit the creating thread's signal mask.

- The new thread sets its signal mask to the desired value using *pthread_sigmask*(3).
- The creating thread restores its signal mask to the original value.

Following the above steps, there is no possibility for the new thread to receive a signal before it has adjusted its signal mask to the desired value.

NAME

pthread_attr_setstack, pthread_attr_getstack − set/get stack attributes in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setstack(pthread_attr_t *attr,
                          void stackaddr[.stacksize],
                          size_t stacksize);
int pthread_attr_getstack(const pthread_attr_t *restrict attr,
                          void **restrict stackaddr,
                          size_t *restrict stacksize);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_attr_getstack(), **pthread_attr_setstack**():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **pthread_attr_setstack**() function sets the stack address and stack size attributes of the thread attributes object referred to by *attr* to the values specified in *stackaddr* and *stacksize*, respectively. These attributes specify the location and size of the stack that should be used by a thread that is created using the thread attributes object *attr*.

stackaddr should point to the lowest addressable byte of a buffer of *stacksize* bytes that was allocated by the caller. The pages of the allocated buffer should be both readable and writable.

The **pthread_attr_getstack**() function returns the stack address and stack size attributes of the thread attributes object referred to by *attr* in the buffers pointed to by *stackaddr* and *stacksize*, respectively.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setstack() can fail with the following error:

EINVAL
: *stacksize* is less than **PTHREAD_STACK_MIN** (16384) bytes. On some systems, this error may also occur if *stackaddr* or *stackaddr* + *stacksize* is not suitably aligned.

POSIX.1 also documents an **EACCES** error if the stack area described by *stackaddr* and *stacksize* is not both readable and writable by the caller.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setstack(), **pthread_attr_getstack**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2. POSIX.1-2001.

NOTES

These functions are provided for applications that must ensure that a thread's stack is placed in a particular location. For most applications, this is not necessary, and the use of these functions should be avoided. (Use *pthread_attr_setstacksize*(3) if an application simply requires a stack size other than the default.)

When an application employs **pthread_attr_setstack**(), it takes over the responsibility of allocating the stack. Any guard size value that was set using *pthread_attr_setguardsize*(3) is ignored. If deemed necessary, it is the application's responsibility to allocate a guard area (one or more pages protected against reading and writing) to handle the possibility of stack overflow.

The address specified in *stackaddr* should be suitably aligned: for full portability, align it on a page

boundary (*sysconf(_SC_PAGESIZE)*). *posix_memalign*(3) may be useful for allocation. Probably, *stacksize* should also be a multiple of the system page size.

If *attr* is used to create multiple threads, then the caller must change the stack address attribute between calls to *pthread_create*(3); otherwise, the threads will attempt to use the same memory area for their stacks, and chaos will ensue.

EXAMPLES

See *pthread_attr_init*(3).

SEE ALSO

mmap(2), *mprotect*(2), *posix_memalign*(3), *pthread_attr_init*(3), *pthread_attr_setguardsize*(3), *pthread_attr_setstackaddr*(3), *pthread_attr_setstacksize*(3), *pthread_create*(3), *pthreads*(7)

NAME

pthread_attr_setstackaddr, pthread_attr_getstackaddr − set/get stack address attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

[[deprecated]]
int pthread_attr_setstackaddr(pthread_attr_t *attr, void *stackaddr);
[[deprecated]]
int pthread_attr_getstackaddr(const pthread_attr_t *restrict attr,
                              void **restrict stackaddr);
```

DESCRIPTION

These functions are obsolete: **do not use them.** Use *pthread_attr_setstack*(3) and *pthread_attr_getstack*(3) instead.

The **pthread_attr_setstackaddr**() function sets the stack address attribute of the thread attributes object referred to by *attr* to the value specified in *stackaddr*. This attribute specifies the location of the stack that should be used by a thread that is created using the thread attributes object *attr*.

stackaddr should point to a buffer of at least **PTHREAD_STACK_MIN** bytes that was allocated by the caller. The pages of the allocated buffer should be both readable and writable.

The **pthread_attr_getstackaddr**() function returns the stack address attribute of the thread attributes object referred to by *attr* in the buffer pointed to by *stackaddr*.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

No errors are defined (but applications should nevertheless handle a possible error return).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setstackaddr(), **pthread_attr_getstackaddr**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

glibc 2.1. Marked obsolete in POSIX.1-2001. Removed in POSIX.1-2008.

NOTES

Do not use these functions! They cannot be portably used, since they provide no way of specifying the direction of growth or the range of the stack. For example, on architectures with a stack that grows downward, *stackaddr* specifies the next address past the *highest* address of the allocated stack area. However, on architectures with a stack that grows upward, *stackaddr* specifies the *lowest* address in the allocated stack area. By contrast, the *stackaddr* used by *pthread_attr_setstack*(3) and *pthread_attr_getstack*(3), is always a pointer to the lowest address in the allocated stack area (and the *stacksize* argument specifies the range of the stack).

SEE ALSO

pthread_attr_init(3), *pthread_attr_setstack*(3), *pthread_attr_setstacksize*(3), *pthread_create*(3), *pthreads*(7)

NAME

pthread_attr_setstacksize, pthread_attr_getstacksize − set/get stack size attribute in thread attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_attr_setstacksize(pthread_attr_t *attr, size_t stacksize);
int pthread_attr_getstacksize(const pthread_attr_t *restrict attr,
                              size_t *restrict stacksize);
```

DESCRIPTION

The **pthread_attr_setstacksize**() function sets the stack size attribute of the thread attributes object referred to by *attr* to the value specified in *stacksize*.

The stack size attribute determines the minimum size (in bytes) that will be allocated for threads created using the thread attributes object *attr*.

The **pthread_attr_getstacksize**() function returns the stack size attribute of the thread attributes object referred to by *attr* in the buffer pointed to by *stacksize*.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

pthread_attr_setstacksize() can fail with the following error:

EINVAL
The stack size is less than **PTHREAD_STACK_MIN** (16384) bytes.

On some systems, **pthread_attr_setstacksize**() can fail with the error **EINVAL** if *stacksize* is not a multiple of the system page size.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_attr_setstacksize(), **pthread_attr_getstacksize**()	Thread safety	MT-Safe

VERSIONS

These functions are provided since glibc 2.1.

STANDARDS

POSIX.1-2001, POSIX.1-2008.

NOTES

For details on the default stack size of new threads, see *pthread_create*(3).

A thread's stack size is fixed at the time of thread creation. Only the main thread can dynamically grow its stack.

The *pthread_attr_setstack*(3) function allows an application to set both the size and location of a caller-allocated stack that is to be used by a thread.

BUGS

As at glibc 2.8, if the specified *stacksize* is not a multiple of **STACK_ALIGN** (16 bytes on most architectures), it may be rounded *downward*, in violation of POSIX.1, which says that the allocated stack will be at least *stacksize* bytes.

EXAMPLES

See *pthread_create*(3).

SEE ALSO

getrlimit(2), *pthread_attr_init*(3), *pthread_attr_setguardsize*(3), *pthread_attr_setstack*(3), *pthread_create*(3), *pthreads*(7)

NAME

pthread_cancel − send a cancelation request to a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_cancel(pthread_t *thread***);**

DESCRIPTION

The **pthread_cancel**() function sends a cancelation request to the thread *thread*. Whether and when the target thread reacts to the cancelation request depends on two attributes that are under the control of that thread: its cancelability *state* and *type*.

A thread's cancelability state, determined by *pthread_setcancelstate*(3), can be *enabled* (the default for new threads) or *disabled*. If a thread has disabled cancelation, then a cancelation request remains queued until the thread enables cancelation. If a thread has enabled cancelation, then its cancelability type determines when cancelation occurs.

A thread's cancelation type, determined by *pthread_setcanceltype*(3), may be either *asynchronous* or *deferred* (the default for new threads). Asynchronous cancelability means that the thread can be canceled at any time (usually immediately, but the system does not guarantee this). Deferred cancelability means that cancelation will be delayed until the thread next calls a function that is a *cancelation point*. A list of functions that are or may be cancelation points is provided in *pthreads*(7).

When a cancelation requested is acted on, the following steps occur for *thread* (in this order):

(1) Cancelation clean-up handlers are popped (in the reverse of the order in which they were pushed) and called. (See *pthread_cleanup_push*(3).)

(2) Thread-specific data destructors are called, in an unspecified order. (See *pthread_key_create*(3).)

(3) The thread is terminated. (See *pthread_exit*(3).)

The above steps happen asynchronously with respect to the **pthread_cancel**() call; the return status of **pthread_cancel**() merely informs the caller whether the cancelation request was successfully queued.

After a canceled thread has terminated, a join with that thread using *pthread_join*(3) obtains **PTHREAD_CANCELED** as the thread's exit status. (Joining with a thread is the only way to know that cancelation has completed.)

RETURN VALUE

On success, **pthread_cancel**() returns 0; on error, it returns a nonzero error number.

ERRORS

ESRCH

No thread with the ID *thread* could be found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_cancel()	Thread safety	MT-Safe

VERSIONS

On Linux, cancelation is implemented using signals. Under the NPTL threading implementation, the first real-time signal (i.e., signal 32) is used for this purpose. On LinuxThreads, the second real-time signal is used, if real-time signals are available, otherwise **SIGUSR2** is used.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.0 POSIX.1-2001.

EXAMPLES

The program below creates a thread and then cancels it. The main thread joins with the canceled thread to check that its exit status was **PTHREAD_CANCELED**. The following shell session shows what happens when we run the program:

```
$ ./a.out
thread_func(): started; cancelation disabled
main(): sending cancelation request
thread_func(): about to enable cancelation
main(): thread was canceled
```

Program source

```
#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

#define handle_error_en(en, msg) \
        do { errno = en; perror(msg); exit(EXIT_FAILURE); } while (0)

static void *
thread_func(void *ignored_argument)
{
    int s;

    /* Disable cancelation for a while, so that we don't
       immediately react to a cancelation request. */

    s = pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
    if (s != 0)
        handle_error_en(s, "pthread_setcancelstate");

    printf("%s(): started; cancelation disabled\n", __func__);
    sleep(5);
    printf("%s(): about to enable cancelation\n", __func__);

    s = pthread_setcancelstate(PTHREAD_CANCEL_ENABLE, NULL);
    if (s != 0)
        handle_error_en(s, "pthread_setcancelstate");

    /* sleep() is a cancelation point. */

    sleep(1000);        /* Should get canceled while we sleep */

    /* Should never get here. */

    printf("%s(): not canceled!\n", __func__);
    return NULL;
}

int
main(void)
{
    pthread_t thr;
    void *res;
    int s;

    /* Start a thread and then send it a cancelation request. */

    s = pthread_create(&thr, NULL, &thread_func, NULL);
    if (s != 0)
        handle_error_en(s, "pthread_create");
```

```
        sleep(2);           /* Give thread a chance to get started */

        printf("%s(): sending cancelation request\n", __func__);
        s = pthread_cancel(thr);
        if (s != 0)
            handle_error_en(s, "pthread_cancel");

        /* Join with thread to see what its exit status was. */

        s = pthread_join(thr, &res);
        if (s != 0)
            handle_error_en(s, "pthread_join");

        if (res == PTHREAD_CANCELED)
            printf("%s(): thread was canceled\n", __func__);
        else
            printf("%s(): thread wasn't canceled (shouldn't happen!)\n",
                    __func__);
        exit(EXIT_SUCCESS);
    }
```

SEE ALSO

pthread_cleanup_push(3), *pthread_create*(3), *pthread_exit*(3), *pthread_join*(3), *pthread_key_create*(3), *pthread_setcancelstate*(3), *pthread_setcanceltype*(3), *pthread_testcancel*(3), *pthreads*(7)

NAME

pthread_cleanup_push, pthread_cleanup_pop − push and pop thread cancelation clean-up handlers

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

void pthread_cleanup_push(void (*routine)(void *), void *arg);
void pthread_cleanup_pop(int execute);
```

DESCRIPTION

These functions manipulate the calling thread's stack of thread-cancelation clean-up handlers. A clean-up handler is a function that is automatically executed when a thread is canceled (or in various other circumstances described below); it might, for example, unlock a mutex so that it becomes available to other threads in the process.

The **pthread_cleanup_push**() function pushes *routine* onto the top of the stack of clean-up handlers. When *routine* is later invoked, it will be given *arg* as its argument.

The **pthread_cleanup_pop**() function removes the routine at the top of the stack of clean-up handlers, and optionally executes it if *execute* is nonzero.

A cancelation clean-up handler is popped from the stack and executed in the following circumstances:

- When a thread is canceled, all of the stacked clean-up handlers are popped and executed in the reverse of the order in which they were pushed onto the stack.
- When a thread terminates by calling *pthread_exit*(3), all clean-up handlers are executed as described in the preceding point. (Clean-up handlers are *not* called if the thread terminates by performing a *return* from the thread start function.)
- When a thread calls **pthread_cleanup_pop**() with a nonzero *execute* argument, the top-most clean-up handler is popped and executed.

POSIX.1 permits **pthread_cleanup_push**() and **pthread_cleanup_pop**() to be implemented as macros that expand to text containing '**{**' and '**}**', respectively. For this reason, the caller must ensure that calls to these functions are paired within the same function, and at the same lexical nesting level. (In other words, a clean-up handler is established only during the execution of a specified section of code.)

Calling *longjmp*(3) (**siglongjmp**(3)) produces undefined results if any call has been made to **pthread_cleanup_push**() or **pthread_cleanup_pop**() without the matching call of the pair since the jump buffer was filled by *setjmp*(3) (**sigsetjmp**(3)). Likewise, calling *longjmp*(3) (**siglongjmp**(3)) from inside a clean-up handler produces undefined results unless the jump buffer was also filled by *setjmp*(3) (**sigsetjmp**(3)) inside the handler.

RETURN VALUE

These functions do not return a value.

ERRORS

There are no errors.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_cleanup_push(), **pthread_cleanup_pop**()	Thread safety	MT-Safe

VERSIONS

On glibc, the **pthread_cleanup_push**() and **pthread_cleanup_pop**() functions *are* implemented as macros that expand to text containing '**{**' and '**}**', respectively. This means that variables declared within the scope of paired calls to these functions will be visible within only that scope.

POSIX.1 says that the effect of using *return*, *break*, *continue*, or *goto* to prematurely leave a block bracketed **pthread_cleanup_push**() and **pthread_cleanup_pop**() is undefined. Portable applications should avoid doing this.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001. glibc 2.0.

EXAMPLES

The program below provides a simple example of the use of the functions described in this page. The program creates a thread that executes a loop bracketed by **pthread_cleanup_push**() and **pthread_cleanup_pop**(). This loop increments a global variable, *cnt*, once each second. Depending on what command-line arguments are supplied, the main thread sends the other thread a cancelation request, or sets a global variable that causes the other thread to exit its loop and terminate normally (by doing a *return*).

In the following shell session, the main thread sends a cancelation request to the other thread:

```
$ ./a.out
New thread started
cnt = 0
cnt = 1
Canceling thread
Called clean-up handler
Thread was canceled; cnt = 0
```

From the above, we see that the thread was canceled, and that the cancelation clean-up handler was called and it reset the value of the global variable *cnt* to 0.

In the next run, the main program sets a global variable that causes other thread to terminate normally:

```
$ ./a.out x
New thread started
cnt = 0
cnt = 1
Thread terminated normally; cnt = 2
```

From the above, we see that the clean-up handler was not executed (because *cleanup_pop_arg* was 0), and therefore the value of *cnt* was not reset.

In the next run, the main program sets a global variable that causes the other thread to terminate normally, and supplies a nonzero value for *cleanup_pop_arg*:

```
$ ./a.out x 1
New thread started
cnt = 0
cnt = 1
Called clean-up handler
Thread terminated normally; cnt = 0
```

In the above, we see that although the thread was not canceled, the clean-up handler was executed, because the argument given to **pthread_cleanup_pop**() was nonzero.

Program source

```
#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/types.h>
#include <unistd.h>

#define handle_error_en(en, msg) \
        do { errno = en; perror(msg); exit(EXIT_FAILURE); } while (0)

static int done = 0;
static int cleanup_pop_arg = 0;
static int cnt = 0;
```

```
static void
cleanup_handler(void *arg)
{
    printf("Called clean-up handler\n");
    cnt = 0;
}

static void *
thread_start(void *arg)
{
    time_t curr;

    printf("New thread started\n");

    pthread_cleanup_push(cleanup_handler, NULL);

    curr = time(NULL);

    while (!done) {
        pthread_testcancel();           /* A cancelation point */
        if (curr < time(NULL)) {
            curr = time(NULL);
            printf("cnt = %d\n", cnt);  /* A cancelation point */
            cnt++;
        }
    }

    pthread_cleanup_pop(cleanup_pop_arg);
    return NULL;
}

int
main(int argc, char *argv[])
{
    pthread_t thr;
    int s;
    void *res;

    s = pthread_create(&thr, NULL, thread_start, NULL);
    if (s != 0)
        handle_error_en(s, "pthread_create");

    sleep(2);           /* Allow new thread to run a while */

    if (argc > 1) {
        if (argc > 2)
            cleanup_pop_arg = atoi(argv[2]);
        done = 1;

    } else {
        printf("Canceling thread\n");
        s = pthread_cancel(thr);
        if (s != 0)
            handle_error_en(s, "pthread_cancel");
    }

    s = pthread_join(thr, &res);
    if (s != 0)
```

```
            handle_error_en(s, "pthread_join");

        if (res == PTHREAD_CANCELED)
            printf("Thread was canceled; cnt = %d\n", cnt);
        else
            printf("Thread terminated normally; cnt = %d\n", cnt);
        exit(EXIT_SUCCESS);
    }
```

NAME

pthread_cleanup_push_defer_np, pthread_cleanup_pop_restore_np − push and pop thread cancelation clean-up handlers while saving cancelability type

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

void pthread_cleanup_push_defer_np(void (**routine***)(void *), void ****arg***);**
void pthread_cleanup_pop_restore_np(int *execute***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_cleanup_push_defer_np(), **pthread_cleanup_pop_defer_np**():
_GNU_SOURCE

DESCRIPTION

These functions are the same as *pthread_cleanup_push*(3) and *pthread_cleanup_pop*(3), except for the differences noted on this page.

Like *pthread_cleanup_push*(3), **pthread_cleanup_push_defer_np**() pushes *routine* onto the thread's stack of cancelation clean-up handlers. In addition, it also saves the thread's current cancelability type, and sets the cancelability type to "deferred" (see *pthread_setcanceltype*(3)); this ensures that cancelation clean-up will occur even if the thread's cancelability type was "asynchronous" before the call.

Like *pthread_cleanup_pop*(3), **pthread_cleanup_pop_restore_np**() pops the top-most clean-up handler from the thread's stack of cancelation clean-up handlers. In addition, it restores the thread's cancelability type to its value at the time of the matching **pthread_cleanup_push_defer_np**().

The caller must ensure that calls to these functions are paired within the same function, and at the same lexical nesting level. Other restrictions apply, as described in *pthread_cleanup_push*(3).

This sequence of calls:

```
pthread_cleanup_push_defer_np(routine, arg);
pthread_cleanup_pop_restore_np(execute);
```

is equivalent to (but shorter and more efficient than):

```
int oldtype;

pthread_cleanup_push(routine, arg);
pthread_setcanceltype(PTHREAD_CANCEL_DEFERRED, &oldtype);
...
pthread_setcanceltype(oldtype, NULL);
pthread_cleanup_pop(execute);
```

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.0

NAME

pthread_cond_init, pthread_cond_signal, pthread_cond_broadcast, pthread_cond_wait, pthread_cond_timedwait, pthread_cond_destroy − operations on conditions

SYNOPSIS

#include <pthread.h>

pthread_cond_t *cond* **= PTHREAD_COND_INITIALIZER;**

int pthread_cond_init(pthread_cond_t ****cond*, pthread_condattr_t ****cond_attr***); int pthread_cond_signal(pthread_cond_t ****cond***); int pthread_cond_broadcast(pthread_cond_t ****cond***); int pthread_cond_wait(pthread_cond_t ****cond***, pthread_mutex_t ****mutex***); int pthread_cond_timedwait(pthread_cond_t ****cond***, pthread_mutex_t ****mutex***, const struct timespec ****abstime***); int pthread_cond_destroy(pthread_cond_t ****cond***);**

DESCRIPTION

A condition (short for ‘‘condition variable’’) is a synchronization device that allows threads to suspend execution and relinquish the processors until some predicate on shared data is satisfied. The basic operations on conditions are: signal the condition (when the predicate becomes true), and wait for the condition, suspending the thread execution until another thread signals the condition.

A condition variable must always be associated with a mutex, to avoid the race condition where a thread prepares to wait on a condition variable and another thread signals the condition just before the first thread actually waits on it.

pthread_cond_init initializes the condition variable *cond*, using the condition attributes specified in *cond_attr*, or default attributes if *cond_attr* is **NULL**. The LinuxThreads implementation supports no attributes for conditions, hence the *cond_attr* parameter is actually ignored.

Variables of type **pthread_cond_t** can also be initialized statically, using the constant **PTHREAD_COND_INITIALIZER**.

pthread_cond_signal restarts one of the threads that are waiting on the condition variable *cond*. If no threads are waiting on *cond*, nothing happens. If several threads are waiting on *cond*, exactly one is restarted, but it is not specified which.

pthread_cond_broadcast restarts all the threads that are waiting on the condition variable *cond*. Nothing happens if no threads are waiting on *cond*.

pthread_cond_wait atomically unlocks the *mutex* (as per **pthread_unlock_mutex**) and waits for the condition variable *cond* to be signaled. The thread execution is suspended and does not consume any CPU time until the condition variable is signaled. The *mutex* must be locked by the calling thread on entrance to **pthread_cond_wait**. Before returning to the calling thread, **pthread_cond_wait** re-acquires *mutex* (as per **pthread_lock_mutex**).

Unlocking the mutex and suspending on the condition variable is done atomically. Thus, if all threads always acquire the mutex before signaling the condition, this guarantees that the condition cannot be signaled (and thus ignored) between the time a thread locks the mutex and the time it waits on the condition variable.

pthread_cond_timedwait atomically unlocks *mutex* and waits on *cond*, as **pthread_cond_wait** does, but it also bounds the duration of the wait. If *cond* has not been signaled within the amount of time specified by *abstime*, the mutex *mutex* is re-acquired and **pthread_cond_timedwait** returns the error **ETIMEDOUT**. The *abstime* parameter specifies an absolute time, with the same origin as **time**(2) and **gettimeofday**(2): an *abstime* of 0 corresponds to 00:00:00 GMT, January 1, 1970.

pthread_cond_destroy destroys a condition variable, freeing the resources it might hold. No threads must be waiting on the condition variable on entrance to **pthread_cond_destroy**. In the LinuxThreads implementation, no resources are associated with condition variables, thus **pthread_cond_destroy** actually does nothing except checking that the condition has no waiting threads.

CANCELLATION

pthread_cond_wait and **pthread_cond_timedwait** are cancelation points. If a thread is cancelled while suspended in one of these functions, the thread immediately resumes execution, then locks again the *mutex* argument to **pthread_cond_wait** and **pthread_cond_timedwait**, and finally executes the cancelation. Consequently, cleanup handlers are assured that *mutex* is locked when they are called.

ASYNC-SIGNAL SAFETY

The condition functions are not async-signal safe, and should not be called from a signal handler. In particular, calling **pthread_cond_signal** or **pthread_cond_broadcast** from a signal handler may deadlock the calling thread.

RETURN VALUE

All condition variable functions return 0 on success and a non-zero error code on error.

ERRORS

pthread_cond_init, **pthread_cond_signal**, **pthread_cond_broadcast**, and **pthread_cond_wait** never return an error code.

The **pthread_cond_timedwait** function returns the following error codes on error:

ETIMEDOUT
The condition variable was not signaled until the timeout specified by *abstime*.

EINTR
pthread_cond_timedwait was interrupted by a signal.

The **pthread_cond_destroy** function returns the following error code on error:

EBUSY
Some threads are currently waiting on *cond*.

SEE ALSO

pthread_condattr_init(3), **pthread_mutex_lock**(3), **pthread_mutex_unlock**(3), **gettimeofday**(2), **nanosleep**(2).

EXAMPLE

Consider two shared variables *x* and *y*, protected by the mutex *mut*, and a condition variable *cond* that is to be signaled whenever *x* becomes greater than *y*.

```
int x,y;
pthread_mutex_t mut = PTHREAD_MUTEX_INITIALIZER;
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

Waiting until *x* is greater than *y* is performed as follows:

```
pthread_mutex_lock(&mut);
while (x <= y) {
    pthread_cond_wait(&cond, &mut);
}
/* operate on x and y */
pthread_mutex_unlock(&mut);
```

Modifications on *x* and *y* that may cause *x* to become greater than *y* should signal the condition if needed:

```
pthread_mutex_lock(&mut);
/* modify x and y */
if (x > y) pthread_cond_broadcast(&cond);
pthread_mutex_unlock(&mut);
```

If it can be proved that at most one waiting thread needs to be waken up (for instance, if there are only two threads communicating through *x* and *y*), **pthread_cond_signal** can be used as a slightly more efficient alternative to **pthread_cond_broadcast**. In doubt, use **pthread_cond_broadcast**.

To wait for *x* to become greater than *y* with a timeout of 5 seconds, do:

```
struct timeval now;
struct timespec timeout;
int retcode;

pthread_mutex_lock(&mut);
gettimeofday(&now);
timeout.tv_sec = now.tv_sec + 5;
timeout.tv_nsec = now.tv_usec * 1000;
retcode = 0;
```

```
while (x <= y && retcode != ETIMEDOUT) {
        retcode = pthread_cond_timedwait(&cond, &mut, &timeout);
}
if (retcode == ETIMEDOUT) {
        /* timeout occurred */
} else {
        /* operate on x and y */
}
pthread_mutex_unlock(&mut);
```

NAME

pthread_condattr_init, pthread_condattr_destroy − condition creation attributes

SYNOPSIS

#include <pthread.h>

int pthread_condattr_init(pthread_condattr_t *_attr_); int pthread_condattr_destroy(pthread_condattr_t *_attr_);

DESCRIPTION

Condition attributes can be specified at condition creation time, by passing a condition attribute object as second argument to **pthread_cond_init**(3). Passing **NULL** is equivalent to passing a condition attribute object with all attributes set to their default values.

The LinuxThreads implementation supports no attributes for conditions. The functions on condition attributes are included only for compliance with the POSIX standard.

pthread_condattr_init initializes the condition attribute object *attr* and fills it with default values for the attributes. **pthread_condattr_destroy** destroys a condition attribute object, which must not be reused until it is reinitialized. Both functions do nothing in the LinuxThreads implementation.

RETURN VALUE

pthread_condattr_init and **pthread_condattr_destroy** always return 0.

SEE ALSO

pthread_cond_init(3).

NAME

pthread_create − create a new thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_create(pthread_t *restrict thread,
                   const pthread_attr_t *restrict attr,
                   void *(*start_routine)(void *),
                   void *restrict arg);
```

DESCRIPTION

The **pthread_create**() function starts a new thread in the calling process. The new thread starts execution by invoking *start_routine*(); *arg* is passed as the sole argument of *start_routine*().

The new thread terminates in one of the following ways:

- It calls *pthread_exit*(3), specifying an exit status value that is available to another thread in the same process that calls *pthread_join*(3).
- It returns from *start_routine*(). This is equivalent to calling *pthread_exit*(3) with the value supplied in the *return* statement.
- It is canceled (see *pthread_cancel*(3)).
- Any of the threads in the process calls *exit*(3), or the main thread performs a return from *main*(). This causes the termination of all threads in the process.

The *attr* argument points to a *pthread_attr_t* structure whose contents are used at thread creation time to determine attributes for the new thread; this structure is initialized using *pthread_attr_init*(3) and related functions. If *attr* is NULL, then the thread is created with default attributes.

Before returning, a successful call to **pthread_create**() stores the ID of the new thread in the buffer pointed to by *thread*; this identifier is used to refer to the thread in subsequent calls to other pthreads functions.

The new thread inherits a copy of the creating thread's signal mask (**pthread_sigmask**(3)). The set of pending signals for the new thread is empty (**sigpending**(2)). The new thread does not inherit the creating thread's alternate signal stack (**sigaltstack**(2)).

The new thread inherits the calling thread's floating-point environment (**fenv**(3)).

The initial value of the new thread's CPU-time clock is 0 (see *pthread_getcpuclockid*(3)).

Linux-specific details

The new thread inherits copies of the calling thread's capability sets (see *capabilities*(7)) and CPU affinity mask (see *sched_setaffinity*(2)).

RETURN VALUE

On success, **pthread_create**() returns 0; on error, it returns an error number, and the contents of **thread* are undefined.

ERRORS

EAGAIN
: Insufficient resources to create another thread.

EAGAIN
: A system-imposed limit on the number of threads was encountered. There are a number of limits that may trigger this error: the **RLIMIT_NPROC** soft resource limit (set via *setrlimit*(2)), which limits the number of processes and threads for a real user ID, was reached; the kernel's system-wide limit on the number of processes and threads, */proc/sys/kernel/threads−max*, was reached (see *proc*(5)); or the maximum number of PIDs, */proc/sys/kernel/pid_max*, was reached (see *proc*(5)).

EINVAL
: Invalid settings in *attr*.

EPERM
No permission to set the scheduling policy and parameters specified in *attr*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_create()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

See *pthread_self*(3) for further information on the thread ID returned in **thread* by **pthread_create**(). Unless real-time scheduling policies are being employed, after a call to **pthread_create**(), it is indeterminate which thread—the caller or the new thread—will next execute.

A thread may either be *joinable* or *detached*. If a thread is joinable, then another thread can call *pthread_join*(3) to wait for the thread to terminate and fetch its exit status. Only when a terminated joinable thread has been joined are the last of its resources released back to the system. When a detached thread terminates, its resources are automatically released back to the system: it is not possible to join with the thread in order to obtain its exit status. Making a thread detached is useful for some types of daemon threads whose exit status the application does not need to care about. By default, a new thread is created in a joinable state, unless *attr* was set to create the thread in a detached state (using *pthread_attr_setdetachstate*(3)).

Under the NPTL threading implementation, if the **RLIMIT_STACK** soft resource limit *at the time the program started* has any value other than "unlimited", then it determines the default stack size of new threads. Using *pthread_attr_setstacksize*(3), the stack size attribute can be explicitly set in the *attr* argument used to create a thread, in order to obtain a stack size other than the default. If the **RLIMIT_STACK** resource limit is set to "unlimited", a per-architecture value is used for the stack size: 2 MB on most architectures; 4 MB on POWER and Sparc-64.

BUGS

In the obsolete LinuxThreads implementation, each of the threads in a process has a different process ID. This is in violation of the POSIX threads specification, and is the source of many other nonconformances to the standard; see *pthreads*(7).

EXAMPLES

The program below demonstrates the use of **pthread_create**(), as well as a number of other functions in the pthreads API.

In the following run, on a system providing the NPTL threading implementation, the stack size defaults to the value given by the "stack size" resource limit:

```
$ ulimit -s
8192            # The stack size limit is 8 MB (0x800000 bytes)
$ ./a.out hola salut servus
Thread 1: top of stack near 0xb7dd03b8; argv_string=hola
Thread 2: top of stack near 0xb75cf3b8; argv_string=salut
Thread 3: top of stack near 0xb6dce3b8; argv_string=servus
Joined with thread 1; returned value was HOLA
Joined with thread 2; returned value was SALUT
Joined with thread 3; returned value was SERVUS
```

In the next run, the program explicitly sets a stack size of 1 MB (using *pthread_attr_setstacksize*(3)) for the created threads:

```
$ ./a.out -s 0x100000 hola salut servus
Thread 1: top of stack near 0xb7d723b8; argv_string=hola
Thread 2: top of stack near 0xb7c713b8; argv_string=salut
Thread 3: top of stack near 0xb7b703b8; argv_string=servus
Joined with thread 1; returned value was HOLA
Joined with thread 2; returned value was SALUT
```

```
    Joined with thread 3; returned value was SERVUS
```

Program source

```
#include <ctype.h>

NAME

pthread_detach − detach a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_detach(pthread_t *thread***);**

DESCRIPTION

The **pthread_detach**() function marks the thread identified by *thread* as detached. When a detached thread terminates, its resources are automatically released back to the system without the need for another thread to join with the terminated thread.

Attempting to detach an already detached thread results in unspecified behavior.

RETURN VALUE

On success, **pthread_detach**() returns 0; on error, it returns an error number.

ERRORS

EINVAL

thread is not a joinable thread.

ESRCH

No thread with the ID *thread* could be found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_detach()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

Once a thread has been detached, it can't be joined with *pthread_join*(3) or be made joinable again.

A new thread can be created in a detached state using *pthread_attr_setdetachstate*(3) to set the detached attribute of the *attr* argument of *pthread_create*(3).

The detached attribute merely determines the behavior of the system when the thread terminates; it does not prevent the thread from being terminated if the process terminates using *exit*(3) (or equivalently, if the main thread returns).

Either *pthread_join*(3) or **pthread_detach**() should be called for each thread that an application creates, so that system resources for the thread can be released. (But note that the resources of any threads for which one of these actions has not been done will be freed when the process terminates.)

EXAMPLES

The following statement detaches the calling thread:

```
pthread_detach(pthread_self());
```

pthread_attr_setdetachstate(3), *pthread_cancel*(3), *pthread_create*(3), *pthread_exit*(3), *pthread_join*(3), *pthreads*(7)

NAME

pthread_equal − compare thread IDs

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_equal(pthread_t *t1*, **pthread_t** *t2*);

DESCRIPTION

The **pthread_equal**() function compares two thread identifiers.

RETURN VALUE

If the two thread IDs are equal, **pthread_equal**() returns a nonzero value; otherwise, it returns 0.

ERRORS

This function always succeeds.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_equal()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

The **pthread_equal**() function is necessary because thread IDs should be considered opaque: there is no portable way for applications to directly compare two *pthread_t* values.

SEE ALSO

pthread_create(3), *pthread_self*(3), *pthreads*(7)

NAME

pthread_exit − terminate calling thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

[[noreturn]] void pthread_exit(void **retval*);

DESCRIPTION

The **pthread_exit**() function terminates the calling thread and returns a value via *retval* that (if the thread is joinable) is available to another thread in the same process that calls *pthread_join*(3).

Any clean-up handlers established by *pthread_cleanup_push*(3) that have not yet been popped, are popped (in the reverse of the order in which they were pushed) and executed. If the thread has any thread-specific data, then, after the clean-up handlers have been executed, the corresponding destructor functions are called, in an unspecified order.

When a thread terminates, process-shared resources (e.g., mutexes, condition variables, semaphores, and file descriptors) are not released, and functions registered using *atexit*(3) are not called.

After the last thread in a process terminates, the process terminates as by calling *exit*(3) with an exit status of zero; thus, process-shared resources are released and functions registered using *atexit*(3) are called.

RETURN VALUE

This function does not return to the caller.

ERRORS

This function always succeeds.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_exit()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

Performing a return from the start function of any thread other than the main thread results in an implicit call to **pthread_exit**(), using the function's return value as the thread's exit status.

To allow other threads to continue execution, the main thread should terminate by calling **pthread_exit**() rather than *exit*(3).

The value pointed to by *retval* should not be located on the calling thread's stack, since the contents of that stack are undefined after the thread terminates.

BUGS

Currently, there are limitations in the kernel implementation logic for *wait*(2)ing on a stopped thread group with a dead thread group leader. This can manifest in problems such as a locked terminal if a stop signal is sent to a foreground process whose thread group leader has already called **pthread_exit**().

SEE ALSO

pthread_create(3), *pthread_join*(3), *pthreads*(7)

NAME

pthread_getattr_default_np, pthread_setattr_default_np, − get or set default thread-creation attributes

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_getattr_default_np(pthread_attr_t *attr);
int pthread_setattr_default_np(const pthread_attr_t *attr);
```

DESCRIPTION

The **pthread_setattr_default_np**() function sets the default attributes used for creation of a new thread—that is, the attributes that are used when *pthread_create*(3) is called with a second argument that is NULL. The default attributes are set using the attributes supplied in **attr*, a previously initialized thread attributes object. Note the following details about the supplied attributes object:

- The attribute settings in the object must be valid.
- The *stack address* attribute must not be set in the object.
- Setting the *stack size* attribute to zero means leave the default stack size unchanged.

The **pthread_getattr_default_np**() function initializes the thread attributes object referred to by *attr* so that it contains the default attributes used for thread creation.

ERRORS

EINVAL
(**pthread_setattr_default_np**()) One of the attribute settings in *attr* is invalid, or the stack address attribute is set in *attr*.

ENOMEM
(**pthread_setattr_default_np**()) Insufficient memory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_getattr_default_np(), **pthread_setattr_default_np**()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in their names.

HISTORY

glibc 2.18.

EXAMPLES

The program below uses **pthread_getattr_default_np**() to fetch the default thread-creation attributes and then displays various settings from the returned thread attributes object. When running the program, we see the following output:

```
$ ./a.out
Stack size:          8388608
Guard size:          4096
Scheduling policy:   SCHED_OTHER
Scheduling priority: 0
Detach state:        JOINABLE
Inherit scheduler:   INHERIT
```

Program source

```
#define _GNU_SOURCE
#include <err.h>
#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>
```

```

NAME

pthread_getattr_np − get attributes of created thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_getattr_np(pthread_t thread, pthread_attr_t *attr);
```

DESCRIPTION

The **pthread_getattr_np**() function initializes the thread attributes object referred to by *attr* so that it contains actual attribute values describing the running thread *thread*.

The returned attribute values may differ from the corresponding attribute values passed in the *attr* object that was used to create the thread using *pthread_create*(3). In particular, the following attributes may differ:

- the detach state, since a joinable thread may have detached itself after creation;
- the stack size, which the implementation may align to a suitable boundary.
- and the guard size, which the implementation may round upward to a multiple of the page size, or ignore (i.e., treat as 0), if the application is allocating its own stack.

Furthermore, if the stack address attribute was not set in the thread attributes object used to create the thread, then the returned thread attributes object will report the actual stack address that the implementation selected for the thread.

When the thread attributes object returned by **pthread_getattr_np**() is no longer required, it should be destroyed using *pthread_attr_destroy*(3).

RETURN VALUE

On success, this function returns 0; on error, it returns a nonzero error number.

ERRORS

ENOMEM
Insufficient memory.

In addition, if *thread* refers to the main thread, then **pthread_getattr_np**() can fail because of errors from various underlying calls: *fopen*(3), if */proc/self/maps* can't be opened; and *getrlimit*(2), if the **RLIMIT_STACK** resource limit is not supported.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_getattr_np()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the name.

HISTORY

glibc 2.2.3.

EXAMPLES

The program below demonstrates the use of **pthread_getattr_np**(). The program creates a thread that then uses **pthread_getattr_np**() to retrieve and display its guard size, stack address, and stack size attributes. Command-line arguments can be used to set these attributes to values other than the default when creating the thread. The shell sessions below demonstrate the use of the program.

In the first run, on an x86-32 system, a thread is created using default attributes:

```
$ ulimit -s      # No stack limit ==> default stack size is 2 MB
unlimited
$ ./a.out
Attributes of created thread:
        Guard size          = 4096 bytes
        Stack address       = 0x40196000 (EOS = 0x40397000)
```

```
        Stack size          = 0x201000 (2101248) bytes
```

In the following run, we see that if a guard size is specified, it is rounded up to the next multiple of the system page size (4096 bytes on x86-32):

```
$ ./a.out -g 4097
Thread attributes object after initializations:
        Guard size          = 4097 bytes
        Stack address       = (nil)
        Stack size          = 0x0 (0) bytes

Attributes of created thread:
        Guard size          = 8192 bytes
        Stack address       = 0x40196000 (EOS = 0x40397000)
        Stack size          = 0x201000 (2101248) bytes
```

In the last run, the program manually allocates a stack for the thread. In this case, the guard size attribute is ignored.

```
$ ./a.out -g 4096 -s 0x8000 -a
Allocated thread stack at 0x804d000

Thread attributes object after initializations:
        Guard size          = 4096 bytes
        Stack address       = 0x804d000 (EOS = 0x8055000)
        Stack size          = 0x8000 (32768) bytes

Attributes of created thread:
        Guard size          = 0 bytes
        Stack address       = 0x804d000 (EOS = 0x8055000)
        Stack size          = 0x8000 (32768) bytes
```

NAME

pthread_getcpuclockid − retrieve ID of a thread's CPU time clock

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>
#include <time.h>

int pthread_getcpuclockid(pthread_t thread, clockid_t *clockid);
```

DESCRIPTION

The **pthread_getcpuclockid**() function obtains the ID of the CPU-time clock of the thread whose ID is given in *thread*, and returns it in the location pointed to by *clockid*.

RETURN VALUE

On success, this function returns 0; on error, it returns a nonzero error number.

ERRORS

ENOENT
: Per-thread CPU time clocks are not supported by the system.

ESRCH
: No thread with the ID *thread* could be found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_getcpuclockid()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2. POSIX.1-2001.

NOTES

When *thread* refers to the calling thread, this function returns an identifier that refers to the same clock manipulated by *clock_gettime*(2) and *clock_settime*(2) when given the clock ID **CLOCK_THREAD_CPUTIME_ID**.

EXAMPLES

The program below creates a thread and then uses *clock_gettime*(2) to retrieve the total process CPU time, and the per-thread CPU time consumed by the two threads. The following shell session shows an example run:

```
$ ./a.out
Main thread sleeping
Subthread starting infinite loop
Main thread consuming some CPU time...
Process total CPU time:    1.368
Main thread CPU time:      0.376
Subthread CPU time:        0.992
```

Program source

```
/* Link with "-lrt" */

#include <errno.h>
#include <pthread.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <time.h>
#include <unistd.h>
```

```
#define handle_error(msg) \
        do { perror(msg); exit(EXIT_FAILURE); } while (0)

#define handle_error_en(en, msg) \
        do { errno = en; perror(msg); exit(EXIT_FAILURE); } while (0)

NAME

pthread_join − join with a terminated thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_join(pthread_t *thread***, void ****retval**);**

DESCRIPTION

The **pthread_join**() function waits for the thread specified by *thread* to terminate. If that thread has already terminated, then **pthread_join**() returns immediately. The thread specified by *thread* must be joinable.

If *retval* is not NULL, then **pthread_join**() copies the exit status of the target thread (i.e., the value that the target thread supplied to *pthread_exit*(3)) into the location pointed to by *retval*. If the target thread was canceled, then **PTHREAD_CANCELED** is placed in the location pointed to by *retval*.

If multiple threads simultaneously try to join with the same thread, the results are undefined. If the thread calling **pthread_join**() is canceled, then the target thread will remain joinable (i.e., it will not be detached).

RETURN VALUE

On success, **pthread_join**() returns 0; on error, it returns an error number.

ERRORS

EDEADLK
A deadlock was detected (e.g., two threads tried to join with each other); or *thread* specifies the calling thread.

EINVAL
thread is not a joinable thread.

EINVAL
Another thread is already waiting to join with this thread.

ESRCH
No thread with the ID *thread* could be found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_join()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

After a successful call to **pthread_join**(), the caller is guaranteed that the target thread has terminated. The caller may then choose to do any clean-up that is required after termination of the thread (e.g., freeing memory or other resources that were allocated to the target thread).

Joining with a thread that has previously been joined results in undefined behavior.

Failure to join with a thread that is joinable (i.e., one that is not detached), produces a "zombie thread". Avoid doing this, since each zombie thread consumes some system resources, and when enough zombie threads have accumulated, it will no longer be possible to create new threads (or processes).

There is no pthreads analog of *waitpid(−1, &status, 0)*, that is, "join with any terminated thread". If you believe you need this functionality, you probably need to rethink your application design.

All of the threads in a process are peers: any thread can join with any other thread in the process.

EXAMPLES

See *pthread_create*(3).

NAME

pthread_key_create, pthread_key_delete, pthread_setspecific, pthread_getspecific − management of thread-specific data

SYNOPSIS

#include <pthread.h>

int pthread_key_create(pthread_key_t *****key**, void (*****destr_function****) (void *));** **int pthread_key_delete(pthread_key_t** *key***);** **int pthread_setspecific(pthread_key_t** *key***, const void *** *pointer***);** **void * pthread_getspecific(pthread_key_t** *key***);**

DESCRIPTION

Programs often need global or static variables that have different values in different threads. Since threads share one memory space, this cannot be achieved with regular variables. Thread-specific data is the POSIX threads answer to this need.

Each thread possesses a private memory block, the thread-specific data area, or TSD area for short. This area is indexed by TSD keys. The TSD area associates values of type **void *** to TSD keys. TSD keys are common to all threads, but the value associated with a given TSD key can be different in each thread.

For concreteness, the TSD areas can be viewed as arrays of **void *** pointers, TSD keys as integer indices into these arrays, and the value of a TSD key as the value of the corresponding array element in the calling thread.

When a thread is created, its TSD area initially associates **NULL** with all keys.

pthread_key_create allocates a new TSD key. The key is stored in the location pointed to by *key*. There is a limit of **PTHREAD_KEYS_MAX** on the number of keys allocated at a given time. The value initially associated with the returned key is **NULL** in all currently executing threads.

The *destr_function* argument, if not **NULL**, specifies a destructor function associated with the key. When a thread terminates via **pthread_exit** or by cancelation, *destr_function* is called with arguments the value associated with the key in that thread. The *destr_function* is not called if that value is **NULL**. The order in which destructor functions are called at thread termination time is unspecified.

Before the destructor function is called, the **NULL** value is associated with the key in the current thread. A destructor function might, however, re-associate non-**NULL** values to that key or some other key. To deal with this, if after all the destructors have been called for all non-**NULL** values, there are still some non-**NULL** values with associated destructors, then the process is repeated. The glibc implementation stops the process after **PTHREAD_DESTRUCTOR_ITERATIONS** iterations, even if some non-**NULL** values with associated descriptors remain. Other implementations may loop indefinitely.

pthread_key_delete deallocates a TSD key. It does not check whether non-**NULL** values are associated with that key in the currently executing threads, nor call the destructor function associated with the key.

pthread_setspecific changes the value associated with *key* in the calling thread, storing the given *pointer* instead.

pthread_getspecific returns the value currently associated with *key* in the calling thread.

RETURN VALUE

pthread_key_create, **pthread_key_delete**, and **pthread_setspecific** return 0 on success and a nonzero error code on failure. If successful, **pthread_key_create** stores the newly allocated key in the location pointed to by its *key* argument.

pthread_getspecific returns the value associated with *key* on success, and **NULL** on error.

ERRORS

pthread_key_create returns the following error code on error:

EAGAIN
PTHREAD_KEYS_MAX keys are already allocated.

pthread_key_delete and **pthread_setspecific** return the following error code on error:

EINVAL
key is not a valid, allocated TSD key.

pthread_getspecific returns **NULL** if *key* is not a valid, allocated TSD key.

SEE ALSO

pthread_create(3), pthread_exit(3), pthread_testcancel(3).

EXAMPLE

The following code fragment allocates a thread-specific array of 100 characters, with automatic reclamation at thread exit:

```
/* Key for the thread-specific buffer */
static pthread_key_t buffer_key;

/* Once-only initialisation of the key */
static pthread_once_t buffer_key_once = PTHREAD_ONCE_INIT;

/* Allocate the thread-specific buffer */
void buffer_alloc(void)
{
  pthread_once(&buffer_key_once, buffer_key_alloc);
  pthread_setspecific(buffer_key, malloc(100));
}

/* Return the thread-specific buffer */
char * get_buffer(void)
{
  return (char *) pthread_getspecific(buffer_key);
}

/* Allocate the key */
static void buffer_key_alloc()
{
  pthread_key_create(&buffer_key, buffer_destroy);
}

/* Free the thread-specific buffer */
static void buffer_destroy(void * buf)
{
  free(buf);
}
```

NAME

pthread_kill − send a signal to a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <signal.h>

int pthread_kill(pthread_t *thread***, int** *sig***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_kill():
_POSIX_C_SOURCE >= 199506L || _XOPEN_SOURCE >= 500

DESCRIPTION

The **pthread_kill**() function sends the signal *sig* to *thread*, a thread in the same process as the caller. The signal is asynchronously directed to *thread*.

If *sig* is 0, then no signal is sent, but error checking is still performed.

RETURN VALUE

On success, **pthread_kill**() returns 0; on error, it returns an error number, and no signal is sent.

ERRORS

EINVAL
An invalid signal was specified.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_kill()	Thread safety	MT-Safe

VERSIONS

The glibc implementation of **pthread_kill**() gives an error (**EINVAL**) on attempts to send either of the real-time signals used internally by the NPTL threading implementation. See *nptl*(7) for details.

POSIX.1-2008 recommends that if an implementation detects the use of a thread ID after the end of its lifetime, **pthread_kill**() should return the error **ESRCH**. The glibc implementation returns this error in the cases where an invalid thread ID can be detected. But note also that POSIX says that an attempt to use a thread ID whose lifetime has ended produces undefined behavior, and an attempt to use an invalid thread ID in a call to **pthread_kill**() can, for example, cause a segmentation fault.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

Signal dispositions are process-wide: if a signal handler is installed, the handler will be invoked in the thread *thread*, but if the disposition of the signal is "stop", "continue", or "terminate", this action will affect the whole process.

kill(2), *sigaction*(2), *sigpending*(2), *pthread_self*(3), *pthread_sigmask*(3), *raise*(3), *pthreads*(7), *signal*(7)

NAME

pthread_kill_other_threads_np − terminate all other threads in process

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

void pthread_kill_other_threads_np(void);

DESCRIPTION

pthread_kill_other_threads_np() has an effect only in the LinuxThreads threading implementation. On that implementation, calling this function causes the immediate termination of all threads in the application, except the calling thread. The cancelation state and cancelation type of the to-be-terminated threads are ignored, and the cleanup handlers are not called in those threads.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_kill_other_threads_np()	Thread safety	MT-Safe

VERSIONS

In the NPTL threading implementation, **pthread_kill_other_threads_np**() exists, but does nothing. (Nothing needs to be done, because the implementation does the right thing during an *execve*(2).)

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the name.

HISTORY

glibc 2.0

NOTES

pthread_kill_other_threads_np() is intended to be called just before a thread calls *execve*(2) or a similar function. This function is designed to address a limitation in the obsolete LinuxThreads implementation whereby the other threads of an application are not automatically terminated (as POSIX.1-2001 requires) during *execve*(2).

SEE ALSO

execve(2), *pthread_cancel*(3), *pthread_setcancelstate*(3), *pthread_setcanceltype*(3), *pthreads*(7)

NAME

pthread_mutex_consistent − make a robust mutex consistent

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_mutex_consistent(pthread_mutex_t ****mutex*);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_mutex_consistent():
_POSIX_C_SOURCE >= 200809L

DESCRIPTION

This function makes a robust mutex consistent if it is in an inconsistent state. A mutex can be left in an inconsistent state if its owner terminates while holding the mutex, in which case the next owner who acquires the mutex will succeed and be notified by a return value of **EOWNERDEAD** from a call to **pthread_mutex_lock**().

RETURN VALUE

On success, *pthread_mutex_consistent*() returns 0. Otherwise, it returns a positive error number to indicate the error.

ERRORS

EINVAL
The mutex is either not robust or is not in an inconsistent state.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.12. POSIX.1-2008.

Before the addition of **pthread_mutex_consistent**() to POSIX, glibc defined the following equivalent nonstandard function if **_GNU_SOURCE** was defined:

[[deprecated]]
int pthread_mutex_consistent_np(const pthread_mutex_t ****mutex*);**

This GNU-specific API, which first appeared in glibc 2.4, is nowadays obsolete and should not be used in new programs; since glibc 2.34 it has been marked as deprecated.

NOTES

pthread_mutex_consistent() simply informs the implementation that the state (shared data) guarded by the mutex has been restored to a consistent state and that normal operations can now be performed with the mutex. It is the application's responsibility to ensure that the shared data has been restored to a consistent state before calling **pthread_mutex_consistent**().

EXAMPLES

See *pthread_mutexattr_setrobust*(3).

SEE ALSO

pthread_mutex_lock(3), *pthread_mutexattr_getrobust*(3), *pthread_mutexattr_init*(3), *pthread_mutexattr_setrobust*(3), *pthreads*(7)

NAME

pthread_mutex_init, pthread_mutex_lock, pthread_mutex_trylock, pthread_mutex_unlock, pthread_mutex_destroy − operations on mutexes

SYNOPSIS

#include <pthread.h>

pthread_mutex_t *fastmutex* **= PTHREAD_MUTEX_INITIALIZER; pthread_mutex_t** *recmutex* **= PTHREAD_RECURSIVE_MUTEX_INITIALIZER_NP; pthread_mutex_t** *errchkmutex* **= PTHREAD_ERRORCHECK_MUTEX_INITIALIZER_NP;**

int pthread_mutex_init(pthread_mutex_t ***_mutex_, const pthread_mutexattr_t ***_mutexattr_**); int pthread_mutex_lock(pthread_mutex_t ***_mutex_**); int pthread_mutex_trylock(pthread_mutex_t ***_mutex_**); int pthread_mutex_unlock(pthread_mutex_t ***_mutex_**); int pthread_mutex_destroy(pthread_mutex_t ***_mutex_**);**

DESCRIPTION

A mutex is a MUTual EXclusion device, and is useful for protecting shared data structures from concurrent modifications, and implementing critical sections and monitors.

A mutex has two possible states: unlocked (not owned by any thread), and locked (owned by one thread). A mutex can never be owned by two different threads simultaneously. A thread attempting to lock a mutex that is already locked by another thread is suspended until the owning thread unlocks the mutex first.

pthread_mutex_init initializes the mutex object pointed to by *mutex* according to the mutex attributes specified in *mutexattr*. If *mutexattr* is **NULL**, default attributes are used instead.

The LinuxThreads implementation supports only one mutex attributes, the *mutex kind*, which is either ‘‘fast’’, ‘‘recursive’’, or ‘‘error checking’’. The kind of a mutex determines whether it can be locked again by a thread that already owns it. The default kind is ‘‘fast’’. See **pthread_mutexattr_init**(3) for more information on mutex attributes.

Variables of type **pthread_mutex_t** can also be initialized statically, using the constants **PTHREAD_MUTEX_INITIALIZER** (for fast mutexes), **PTHREAD_RECURSIVE_MUTEX_INITIALIZER_NP** (for recursive mutexes), and **PTHREAD_ERRORCHECK_MUTEX_INITIALIZER_NP** (for error checking mutexes).

pthread_mutex_lock locks the given mutex. If the mutex is currently unlocked, it becomes locked and owned by the calling thread, and **pthread_mutex_lock** returns immediately. If the mutex is already locked by another thread, **pthread_mutex_lock** suspends the calling thread until the mutex is unlocked.

If the mutex is already locked by the calling thread, the behavior of **pthread_mutex_lock** depends on the kind of the mutex. If the mutex is of the ‘‘fast’’ kind, the calling thread is suspended until the mutex is unlocked, thus effectively causing the calling thread to deadlock. If the mutex is of the ‘‘error checking’’ kind, **pthread_mutex_lock** returns immediately with the error code **EDEADLK**. If the mutex is of the ‘‘recursive’’ kind, **pthread_mutex_lock** succeeds and returns immediately, recording the number of times the calling thread has locked the mutex. An equal number of **pthread_mutex_unlock** operations must be performed before the mutex returns to the unlocked state.

pthread_mutex_trylock behaves identically to **pthread_mutex_lock**, except that it does not block the calling thread if the mutex is already locked by another thread (or by the calling thread in the case of a ‘‘fast’’ mutex). Instead, **pthread_mutex_trylock** returns immediately with the error code **EBUSY**.

pthread_mutex_unlock unlocks the given mutex. The mutex is assumed to be locked and owned by the calling thread on entrance to **pthread_mutex_unlock**. If the mutex is of the ‘‘fast’’ kind, **pthread_mutex_unlock** always returns it to the unlocked state. If it is of the ‘‘recursive’’ kind, it decrements the locking count of the mutex (number of **pthread_mutex_lock** operations performed on it by the calling thread), and only when this count reaches zero is the mutex actually unlocked.

On ‘‘error checking’’ and ‘‘recursive’’ mutexes, **pthread_mutex_unlock** actually checks at run-time that the mutex is locked on entrance, and that it was locked by the same thread that is now calling **pthread_mutex_unlock**. If these conditions are not met, an error code is returned and the mutex remains unchanged. ‘‘Fast’’ mutexes perform no such checks, thus allowing a locked mutex to be unlocked by a thread other than its owner. This is non-portable behavior and must not be relied upon.

pthread_mutex_destroy destroys a mutex object, freeing the resources it might hold. The mutex must be unlocked on entrance. In the LinuxThreads implementation, no resources are associated with mutex objects, thus **pthread_mutex_destroy** actually does nothing except checking that the mutex is unlocked.

CANCELLATION

None of the mutex functions is a cancelation point, not even **pthread_mutex_lock**, in spite of the fact that it can suspend a thread for arbitrary durations. This way, the status of mutexes at cancelation points is predictable, allowing cancelation handlers to unlock precisely those mutexes that need to be unlocked before the thread stops executing. Consequently, threads using deferred cancelation should never hold a mutex for extended periods of time.

ASYNC-SIGNAL SAFETY

The mutex functions are not async-signal safe. What this means is that they should not be called from a signal handler. In particular, calling **pthread_mutex_lock** or **pthread_mutex_unlock** from a signal handler may deadlock the calling thread.

RETURN VALUE

pthread_mutex_init always returns 0. The other mutex functions return 0 on success and a non-zero error code on error.

ERRORS

The **pthread_mutex_lock** function returns the following error code on error:

EINVAL
The mutex has not been properly initialized.

EDEADLK
The mutex is already locked by the calling thread (‘‘error checking’’ mutexes only).

The **pthread_mutex_trylock** function returns the following error codes on error:

EBUSY
The mutex could not be acquired because it was currently locked.

EINVAL
The mutex has not been properly initialized.

The **pthread_mutex_unlock** function returns the following error code on error:

EINVAL
The mutex has not been properly initialized.

EPERM
The calling thread does not own the mutex (‘‘error checking’’ mutexes only).

The **pthread_mutex_destroy** function returns the following error code on error:

EBUSY
The mutex is currently locked.

SEE ALSO

pthread_mutexattr_init(3), **pthread_mutexattr_setkind_np**(3), **pthread_cancel**(3).

EXAMPLE

A shared global variable *x* can be protected by a mutex as follows:

```
int x;
pthread_mutex_t mut = PTHREAD_MUTEX_INITIALIZER;
```

All accesses and modifications to *x* should be bracketed by calls to **pthread_mutex_lock** and **pthread_mutex_unlock** as follows:

```
pthread_mutex_lock(&mut);
/* operate on x */
pthread_mutex_unlock(&mut);
```

NAME

pthread_mutexattr_getpshared, pthread_mutexattr_setpshared − get/set process-shared mutex attribute

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_mutexattr_getpshared(
        const pthread_mutexattr_t *restrict attr,
        int *restrict pshared);
int pthread_mutexattr_setpshared(pthread_mutexattr_t *attr,
        int pshared);
```

DESCRIPTION

These functions get and set the process-shared attribute in a mutex attributes object. This attribute must be appropriately set to ensure correct, efficient operation of a mutex created using this attributes object.

The process-shared attribute can have one of the following values:

PTHREAD_PROCESS_PRIVATE
: Mutexes created with this attributes object are to be shared only among threads in the same process that initialized the mutex. This is the default value for the process-shared mutex attribute.

PTHREAD_PROCESS_SHARED
: Mutexes created with this attributes object can be shared between any threads that have access to the memory containing the object, including threads in different processes.

pthread_mutexattr_getpshared() places the value of the process-shared attribute of the mutex attributes object referred to by *attr* in the location pointed to by *pshared*.

pthread_mutexattr_setpshared() sets the value of the process-shared attribute of the mutex attributes object referred to by *attr* to the value specified in **pshared**.

If *attr* does not refer to an initialized mutex attributes object, the behavior is undefined.

RETURN VALUE

On success, these functions return 0. On error, they return a positive error number.

ERRORS

pthread_mutexattr_setpshared() can fail with the following errors:

EINVAL
: The value specified in *pshared* is invalid.

ENOTSUP
: *pshared is* **PTHREAD_PROCESS_SHARED** but the implementation does not support process-shared mutexes.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

SEE ALSO

pthread_mutexattr_init(3), *pthreads*(7)

NAME

pthread_mutexattr_init, pthread_mutexattr_destroy − initialize and destroy a mutex attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_mutexattr_init(pthread_mutexattr_t *attr);
int pthread_mutexattr_destroy(pthread_mutexattr_t *attr);
```

DESCRIPTION

The **pthread_mutexattr_init**() function initializes the mutex attributes object pointed to by *attr* with default values for all attributes defined by the implementation.

The results of initializing an already initialized mutex attributes object are undefined.

The **pthread_mutexattr_destroy**() function destroys a mutex attribute object (making it uninitialized). Once a mutex attributes object has been destroyed, it can be reinitialized with **pthread_mutexattr_init**().

The results of destroying an uninitialized mutex attributes object are undefined.

RETURN VALUE

On success, these functions return 0. On error, they return a positive error number.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

Subsequent changes to a mutex attributes object do not affect mutex that have already been initialized using that object.

SEE ALSO

pthread_mutex_init(3), *pthread_mutexattr_getpshared*(3), *pthread_mutexattr_getrobust*(3), *pthreads*(7)

NAME

pthread_mutexattr_setkind_np, pthread_mutexattr_getkind_np − deprecated mutex creation attributes

SYNOPSIS

#include <pthread.h>

int pthread_mutexattr_setkind_np(pthread_mutexattr_t **attr*, int *kind*); int pthread_mutexattr_getkind_np(const pthread_mutexattr_t **attr*, int **kind*);

DESCRIPTION

These functions are deprecated, use **pthread_mutexattr_settype**(3) and **pthread_mutexattr_gettype**(3) instead.

RETURN VALUE

pthread_mutexattr_getkind_np always returns 0.

pthread_mutexattr_setkind_np returns 0 on success and a non-zero error code on error.

ERRORS

On error, **pthread_mutexattr_setkind_np** returns the following error code:

EINVAL

kind is neither **PTHREAD_MUTEX_FAST_NP** nor **PTHREAD_MUTEX_RECURSIVE_NP** nor **PTHREAD_MUTEX_ERRORCHECK_NP**.

SEE ALSO

pthread_mutexattr_settype(3), **pthread_mutexattr_gettype**(3).

NAME

pthread_mutexattr_getrobust, pthread_mutexattr_setrobust − get and set the robustness attribute of a mutex attributes object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_mutexattr_getrobust(const pthread_mutexattr_t *attr,
                                int *robustness);
int pthread_mutexattr_setrobust(pthread_mutexattr_t *attr,
                                int robustness);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_mutexattr_getrobust(), **pthread_mutexattr_setrobust**():
_POSIX_C_SOURCE >= 200809L

DESCRIPTION

The **pthread_mutexattr_getrobust**() function places the value of the robustness attribute of the mutex attributes object referred to by *attr* in **robustness*. The **pthread_mutexattr_setrobust**() function sets the value of the robustness attribute of the mutex attributes object referred to by *attr* to the value specified in **robustness*.

The robustness attribute specifies the behavior of the mutex when the owning thread dies without unlocking the mutex. The following values are valid for *robustness*:

PTHREAD_MUTEX_STALLED
: This is the default value for a mutex attributes object. If a mutex is initialized with the **PTHREAD_MUTEX_STALLED** attribute and its owner dies without unlocking it, the mutex remains locked afterwards and any future attempts to call *pthread_mutex_lock*(3) on the mutex will block indefinitely.

PTHREAD_MUTEX_ROBUST
: If a mutex is initialized with the **PTHREAD_MUTEX_ROBUST** attribute and its owner dies without unlocking it, any future attempts to call *pthread_mutex_lock*(3) on this mutex will succeed and return **EOWNERDEAD** to indicate that the original owner no longer exists and the mutex is in an inconsistent state. Usually after **EOWNERDEAD** is returned, the next owner should call *pthread_mutex_consistent*(3) on the acquired mutex to make it consistent again before using it any further.

  If the next owner unlocks the mutex using *pthread_mutex_unlock*(3) before making it consistent, the mutex will be permanently unusable and any subsequent attempts to lock it using *pthread_mutex_lock*(3) will fail with the error **ENOTRECOVERABLE**. The only permitted operation on such a mutex is *pthread_mutex_destroy*(3)

  If the next owner terminates before calling *pthread_mutex_consistent*(3), further *pthread_mutex_lock*(3) operations on this mutex will still return **EOWNERDEAD**.

Note that the *attr* argument of **pthread_mutexattr_getrobust**() and **pthread_mutexattr_setrobust**() should refer to a mutex attributes object that was initialized by *pthread_mutexattr_init*(3), otherwise the behavior is undefined.

RETURN VALUE

On success, these functions return 0. On error, they return a positive error number.

In the glibc implementation, **pthread_mutexattr_getrobust**() always return zero.

ERRORS

EINVAL
: A value other than **PTHREAD_MUTEX_STALLED** or **PTHREAD_MUTEX_ROBUST** was passed to **pthread_mutexattr_setrobust**().

VERSIONS

In the Linux implementation, when using process-shared robust mutexes, a waiting thread also receives the **EOWNERDEAD** notification if the owner of a robust mutex performs an *execve*(2) without first

unlocking the mutex. POSIX.1 does not specify this detail, but the same behavior also occurs in at least some other implementations.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.12. POSIX.1-2008.

Before the addition of **pthread_mutexattr_getrobust**() and **pthread_mutexattr_setrobust**() to POSIX, glibc defined the following equivalent nonstandard functions if **_GNU_SOURCE** was defined:

[[deprecated]]
int pthread_mutexattr_getrobust_np(const pthread_mutexattr_t ****attr*,**
int ****robustness*);**
[[deprecated]]
int pthread_mutexattr_setrobust_np(const pthread_mutexattr_t ****attr*,**
int *robustness***);**

Correspondingly, the constants **PTHREAD_MUTEX_STALLED_NP** and **PTHREAD_MUTEX_ROBUST_NP** were also defined.

These GNU-specific APIs, which first appeared in glibc 2.4, are nowadays obsolete and should not be used in new programs; since glibc 2.34 these APIs are marked as deprecated.

EXAMPLES

The program below demonstrates the use of the robustness attribute of a mutex attributes object. In this program, a thread holding the mutex dies prematurely without unlocking the mutex. The main thread subsequently acquires the mutex successfully and gets the error **EOWNERDEAD**, after which it makes the mutex consistent.

The following shell session shows what we see when running this program:

```
$ ./a.out
[original owner] Setting lock...
[original owner] Locked. Now exiting without unlocking.
[main] Attempting to lock the robust mutex.
[main] pthread_mutex_lock() returned EOWNERDEAD
[main] Now make the mutex consistent
[main] Mutex is now consistent; unlocking
```

Program source

```
#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

#define handle_error_en(en, msg) \
        do { errno = en; perror(msg); exit(EXIT_FAILURE); } while (0)

static pthread_mutex_t mtx;

static void *
original_owner_thread(void *ptr)
{
    printf("[original owner] Setting lock...\n");
    pthread_mutex_lock(&mtx);
    printf("[original owner] Locked. Now exiting without unlocking.\n");
    pthread_exit(NULL);
}

int
main(void)
{
```

```
        pthread_t thr;
        pthread_mutexattr_t attr;
        int s;

        pthread_mutexattr_init(&attr);

        pthread_mutexattr_setrobust(&attr, PTHREAD_MUTEX_ROBUST);

        pthread_mutex_init(&mtx, &attr);

        pthread_create(&thr, NULL, original_owner_thread, NULL);

        sleep(2);

        /* "original_owner_thread" should have exited by now. */

        printf("[main] Attempting to lock the robust mutex.\n");
        s = pthread_mutex_lock(&mtx);
        if (s == EOWNERDEAD) {
            printf("[main] pthread_mutex_lock() returned EOWNERDEAD\n");
            printf("[main] Now make the mutex consistent\n");
            s = pthread_mutex_consistent(&mtx);
            if (s != 0)
                handle_error_en(s, "pthread_mutex_consistent");
            printf("[main] Mutex is now consistent; unlocking\n");
            s = pthread_mutex_unlock(&mtx);
            if (s != 0)
                handle_error_en(s, "pthread_mutex_unlock");

            exit(EXIT_SUCCESS);
        } else if (s == 0) {
            printf("[main] pthread_mutex_lock() unexpectedly succeeded\n");
            exit(EXIT_FAILURE);
        } else {
            printf("[main] pthread_mutex_lock() unexpectedly failed\n");
            handle_error_en(s, "pthread_mutex_lock");
        }
    }
```

NAME

pthread_once − once-only initialization

SYNOPSIS

#include <pthread.h>

pthread_once_t *once_control* **= PTHREAD_ONCE_INIT;**

int pthread_once(pthread_once_t ***_once_control_, void (***_init_routine_**) (void));**

DESCRIPTION

The purpose of **pthread_once** is to ensure that a piece of initialization code is executed at most once. The *once_control* argument points to a static or extern variable statically initialized to **PTHREAD_ONCE_INIT**.

The first time **pthread_once** is called with a given *once_control* argument, it calls *init_routine* with no argument and changes the value of the *once_control* variable to record that initialization has been performed. Subsequent calls to **pthread_once** with the same **once_control** argument do nothing.

RETURN VALUE

pthread_once always returns 0.

ERRORS

None.

NAME

pthread_rwlockattr_setkind_np, pthread_rwlockattr_getkind_np − set/get the read-write lock kind of the thread read-write lock attribute object

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_rwlockattr_setkind_np(pthread_rwlockattr_t *attr,
                                  int pref);
int pthread_rwlockattr_getkind_np(
                                  const pthread_rwlockattr_t *restrict attr,
                                  int *restrict pref);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_rwlockattr_setkind_np(), **pthread_rwlockattr_getkind_np**():
_XOPEN_SOURCE >= 500 || _POSIX_C_SOURCE >= 200809L

DESCRIPTION

The **pthread_rwlockattr_setkind_np**() function sets the "lock kind" attribute of the read-write lock attribute object referred to by *attr* to the value specified in *pref*. The argument *pref* may be set to one of the following:

PTHREAD_RWLOCK_PREFER_READER_NP
: This is the default. A thread may hold multiple read locks; that is, read locks are recursive. According to The Single Unix Specification, the behavior is unspecified when a reader tries to place a lock, and there is no write lock but writers are waiting. Giving preference to the reader, as is set by **PTHREAD_RWLOCK_PREFER_READER_NP**, implies that the reader will receive the requested lock, even if a writer is waiting. As long as there are readers, the writer will be starved.

PTHREAD_RWLOCK_PREFER_WRITER_NP
: This is intended as the write lock analog of **PTHREAD_RWLOCK_PREFER_READER_NP**. This is ignored by glibc because the POSIX requirement to support recursive read locks would cause this option to create trivial deadlocks; instead use **PTHREAD_RWLOCK_PREFER_WRITER_NONRECURSIVE_NP** which ensures the application developer will not take recursive read locks thus avoiding deadlocks.

PTHREAD_RWLOCK_PREFER_WRITER_NONRECURSIVE_NP
: Setting the lock kind to this avoids writer starvation as long as any read locking is not done in a recursive fashion.

The **pthread_rwlockattr_getkind_np**() function returns the value of the lock kind attribute of the read-write lock attribute object referred to by *attr* in the pointer *pref*.

RETURN VALUE

On success, these functions return 0. Given valid pointer arguments, **pthread_rwlockattr_getkind_np**() always succeeds. On error, **pthread_rwlockattr_setkind_np**() returns a nonzero error number.

ERRORS

EINVAL
: *pref* specifies an unsupported value.

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.1.

SEE ALSO

pthreads(7)

NAME

pthread_self − obtain ID of the calling thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

pthread_t pthread_self(void);

DESCRIPTION

The **pthread_self**() function returns the ID of the calling thread. This is the same value that is returned in **thread* in the *pthread_create*(3) call that created this thread.

RETURN VALUE

This function always succeeds, returning the calling thread's ID.

ERRORS

This function always succeeds.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_self()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

POSIX.1 allows an implementation wide freedom in choosing the type used to represent a thread ID; for example, representation using either an arithmetic type or a structure is permitted. Therefore, variables of type *pthread_t* can't portably be compared using the C equality operator (==); use *pthread_equal*(3) instead.

Thread identifiers should be considered opaque: any attempt to use a thread ID other than in pthreads calls is nonportable and can lead to unspecified results.

Thread IDs are guaranteed to be unique only within a process. A thread ID may be reused after a terminated thread has been joined, or a detached thread has terminated.

The thread ID returned by **pthread_self**() is not the same thing as the kernel thread ID returned by a call to *gettid*(2).

SEE ALSO

pthread_create(3), *pthread_equal*(3), *pthreads*(7)

NAME

pthread_setaffinity_np, pthread_getaffinity_np − set/get CPU affinity of a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_setaffinity_np(pthread_t thread, size_t cpusetsize,
                           const cpu_set_t *cpuset);
int pthread_getaffinity_np(pthread_t thread, size_t cpusetsize,
                           cpu_set_t *cpuset);
```

DESCRIPTION

The **pthread_setaffinity_np**() function sets the CPU affinity mask of the thread *thread* to the CPU set pointed to by *cpuset*. If the call is successful, and the thread is not currently running on one of the CPUs in *cpuset*, then it is migrated to one of those CPUs.

The **pthread_getaffinity_np**() function returns the CPU affinity mask of the thread *thread* in the buffer pointed to by *cpuset*.

For more details on CPU affinity masks, see *sched_setaffinity*(2). For a description of a set of macros that can be used to manipulate and inspect CPU sets, see *CPU_SET*(3).

The argument *cpusetsize* is the length (in bytes) of the buffer pointed to by *cpuset*. Typically, this argument would be specified as *sizeof(cpu_set_t)*. (It may be some other value, if using the macros described in *CPU_SET*(3) for dynamically allocating a CPU set.)

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

EFAULT
: A supplied memory address was invalid.

EINVAL
: (**pthread_setaffinity_np**()) The affinity bit mask *mask* contains no processors that are currently physically on the system and permitted to the thread according to any restrictions that may be imposed by the "cpuset" mechanism described in *cpuset*(7).

EINVAL
: (**pthread_setaffinity_np**()) *cpuset* specified a CPU that was outside the set supported by the kernel. (The kernel configuration option **CONFIG_NR_CPUS** defines the range of the set supported by the kernel data type used to represent CPU sets.)

EINVAL
: (**pthread_getaffinity_np**()) *cpusetsize* is smaller than the size of the affinity mask used by the kernel.

ESRCH
: No thread with the ID *thread* could be found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_setaffinity_np(), **pthread_getaffinity_np**()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.3.4.

In glibc 2.3.3 only, versions of these functions were provided that did not have a *cpusetsize* argument. Instead the CPU set size given to the underlying system calls was always *sizeof(cpu_set_t)*.

NOTES

After a call to **pthread_setaffinity_np**(), the set of CPUs on which the thread will actually run is the intersection of the set specified in the *cpuset* argument and the set of CPUs actually present on the system. The system may further restrict the set of CPUs on which the thread runs if the "cpuset" mechanism described in *cpuset*(7) is being used. These restrictions on the actual set of CPUs on which the thread will run are silently imposed by the kernel.

These functions are implemented on top of the *sched_setaffinity*(2) and *sched_getaffinity*(2) system calls.

A new thread created by *pthread_create*(3) inherits a copy of its creator's CPU affinity mask.

EXAMPLES

In the following program, the main thread uses **pthread_setaffinity_np**() to set its CPU affinity mask to include CPUs 0 to 7 (which may not all be available on the system), and then calls **pthread_getaffinity_np**() to check the resulting CPU affinity mask of the thread.

```
#define _GNU_SOURCE
#include <err.h>
#include <errno.h>
#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    int s;
    cpu_set_t cpuset;
    pthread_t thread;

    thread = pthread_self();

    /* Set affinity mask to include CPUs 0 to 7. */

    CPU_ZERO(&cpuset);
    for (size_t j = 0; j < 8; j++)
        CPU_SET(j, &cpuset);

    s = pthread_setaffinity_np(thread, sizeof(cpuset), &cpuset);
    if (s != 0)
        errc(EXIT_FAILURE, s, "pthread_setaffinity_np");

    /* Check the actual affinity mask assigned to the thread. */

    s = pthread_getaffinity_np(thread, sizeof(cpuset), &cpuset);
    if (s != 0)
        errc(EXIT_FAILURE, s, "pthread_getaffinity_np");

    printf("Set returned by pthread_getaffinity_np() contained:\n");
    for (size_t j = 0; j < CPU_SETSIZE; j++)
        if (CPU_ISSET(j, &cpuset))
            printf("    CPU %zu\n", j);

    exit(EXIT_SUCCESS);
}
```

NAME

pthread_setcancelstate, pthread_setcanceltype − set cancelability state and type

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_setcancelstate(int *state***, int ****oldstate***);**
int pthread_setcanceltype(int *type***, int ****oldtype***);**

DESCRIPTION

The **pthread_setcancelstate**() sets the cancelability state of the calling thread to the value given in *state*. The previous cancelability state of the thread is returned in the buffer pointed to by *oldstate*. The *state* argument must have one of the following values:

PTHREAD_CANCEL_ENABLE
: The thread is cancelable. This is the default cancelability state in all new threads, including the initial thread. The thread's cancelability type determines when a cancelable thread will respond to a cancelation request.

PTHREAD_CANCEL_DISABLE
: The thread is not cancelable. If a cancelation request is received, it is blocked until cancelability is enabled.

The **pthread_setcanceltype**() sets the cancelability type of the calling thread to the value given in *type*. The previous cancelability type of the thread is returned in the buffer pointed to by *oldtype*. The *type* argument must have one of the following values:

PTHREAD_CANCEL_DEFERRED
: A cancelation request is deferred until the thread next calls a function that is a cancelation point (see *pthreads*(7)). This is the default cancelability type in all new threads, including the initial thread.

  Even with deferred cancelation, a cancelation point in an asynchronous signal handler may still be acted upon and the effect is as if it was an asynchronous cancelation.

PTHREAD_CANCEL_ASYNCHRONOUS
: The thread can be canceled at any time. (Typically, it will be canceled immediately upon receiving a cancelation request, but the system doesn't guarantee this.)

The set-and-get operation performed by each of these functions is atomic with respect to other threads in the process calling the same function.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

The **pthread_setcancelstate**() can fail with the following error:

EINVAL
: Invalid value for *state*.

The **pthread_setcanceltype**() can fail with the following error:

EINVAL
: Invalid value for *type*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_setcancelstate(), **pthread_setcanceltype**()	Thread safety	MT-Safe
pthread_setcancelstate(), **pthread_setcanceltype**()	Async-cancel safety	AC-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.0 POSIX.1-2001.

NOTES

For details of what happens when a thread is canceled, see **pthread_cancel**(3).

Briefly disabling cancelability is useful if a thread performs some critical action that must not be interrupted by a cancelation request. Beware of disabling cancelability for long periods, or around operations that may block for long periods, since that will render the thread unresponsive to cancelation requests.

Asynchronous cancelability

Setting the cancelability type to **PTHREAD_CANCEL_ASYNCHRONOUS** is rarely useful. Since the thread could be canceled at *any* time, it cannot safely reserve resources (e.g., allocating memory with *malloc*(3)), acquire mutexes, semaphores, or locks, and so on. Reserving resources is unsafe because the application has no way of knowing what the state of these resources is when the thread is canceled; that is, did cancelation occur before the resources were reserved, while they were reserved, or after they were released? Furthermore, some internal data structures (e.g., the linked list of free blocks managed by the *malloc*(3) family of functions) may be left in an inconsistent state if cancelation occurs in the middle of the function call. Consequently, clean-up handlers cease to be useful.

Functions that can be safely asynchronously canceled are called *async-cancel-safe functions*. POSIX.1-2001 and POSIX.1-2008 require only that *pthread_cancel*(3), **pthread_setcancelstate**(), and **pthread_setcanceltype**() be async-cancel-safe. In general, other library functions can't be safely called from an asynchronously cancelable thread.

One of the few circumstances in which asynchronous cancelability is useful is for cancelation of a thread that is in a pure compute-bound loop.

Portability notes

The Linux threading implementations permit the *oldstate* argument of **pthread_setcancelstate**() to be NULL, in which case the information about the previous cancelability state is not returned to the caller. Many other implementations also permit a NULL *oldstat* argument, but POSIX.1 does not specify this point, so portable applications should always specify a non-NULL value in *oldstate*. A precisely analogous set of statements applies for the *oldtype* argument of **pthread_setcanceltype**().

EXAMPLES

See *pthread_cancel*(3).

NAME

pthread_setconcurrency, pthread_getconcurrency − set/get the concurrency level

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_setconcurrency(int *new_level***);**
int pthread_getconcurrency(*void***);**

DESCRIPTION

The **pthread_setconcurrency**() function informs the implementation of the application's desired concurrency level, specified in *new_level*. The implementation takes this only as a hint: POSIX.1 does not specify the level of concurrency that should be provided as a result of calling **pthread_setconcurrency**().

Specifying *new_level* as 0 instructs the implementation to manage the concurrency level as it deems appropriate.

pthread_getconcurrency() returns the current value of the concurrency level for this process.

RETURN VALUE

On success, **pthread_setconcurrency**() returns 0; on error, it returns a nonzero error number.

pthread_getconcurrency() always succeeds, returning the concurrency level set by a previous call to **pthread_setconcurrency**(), or 0, if **pthread_setconcurrency**() has not previously been called.

ERRORS

pthread_setconcurrency() can fail with the following error:

EINVAL
new_level is negative.

POSIX.1 also documents an **EAGAIN** error ("the value specified by *new_level* would cause a system resource to be exceeded").

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_setconcurrency(), **pthread_getconcurrency**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.1. POSIX.1-2001.

NOTES

The default concurrency level is 0.

Concurrency levels are meaningful only for M:N threading implementations, where at any moment a subset of a process's set of user-level threads may be bound to a smaller number of kernel-scheduling entities. Setting the concurrency level allows the application to give the system a hint as to the number of kernel-scheduling entities that should be provided for efficient execution of the application.

Both LinuxThreads and NPTL are 1:1 threading implementations, so setting the concurrency level has no meaning. In other words, on Linux these functions merely exist for compatibility with other systems, and they have no effect on the execution of a program.

SEE ALSO

pthread_attr_setscope(3), *pthreads*(7)

NAME

pthread_setname_np, pthread_getname_np − set/get the name of a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_setname_np(pthread_t thread, const char *name);
int pthread_getname_np(pthread_t thread, char name[.size], size_t size);
```

DESCRIPTION

By default, all the threads created using **pthread_create**() inherit the program name. The **pthread_setname_np**() function can be used to set a unique name for a thread, which can be useful for debugging multithreaded applications. The thread name is a meaningful C language string, whose length is restricted to 16 characters, including the terminating null byte ('\0'). The *thread* argument specifies the thread whose name is to be changed; *name* specifies the new name.

The **pthread_getname_np**() function can be used to retrieve the name of the thread. The *thread* argument specifies the thread whose name is to be retrieved. The buffer *name* is used to return the thread name; *size* specifies the number of bytes available in *name*. The buffer specified by *name* should be at least 16 characters in length. The returned thread name in the output buffer will be null terminated.

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number.

ERRORS

The **pthread_setname_np**() function can fail with the following error:

ERANGE
: The length of the string specified pointed to by *name* exceeds the allowed limit.

The **pthread_getname_np**() function can fail with the following error:

ERANGE
: The buffer specified by *name* and *size* is too small to hold the thread name.

If either of these functions fails to open */proc/self/task/*tid*/comm*, then the call may fail with one of the errors described in *open*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_setname_np(), **pthread_getname_np**()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.12.

NOTES

pthread_setname_np() internally writes to the thread-specific *comm* file under the */proc* filesystem: */proc/self/task/*tid*/comm*. **pthread_getname_np**() retrieves it from the same location.

EXAMPLES

The program below demonstrates the use of **pthread_setname_np**() and **pthread_getname_np**().

The following shell session shows a sample run of the program:

```
$ ./a.out
Created a thread. Default name is: a.out
The thread name after setting it is THREADFOO.
^Z                              # Suspend the program
[1]+  Stopped                 ./a.out
$ ps H -C a.out -o 'pid tid cmd comm'
  PID   TID CMD                         COMMAND
```

```
 5990  5990 ./a.out                    a.out
 5990  5991 ./a.out                    THREADFOO
$ cat /proc/5990/task/5990/comm
a.out
$ cat /proc/5990/task/5991/comm
THREADFOO
```

Program source

```

NAME

pthread_setschedparam, pthread_getschedparam − set/get scheduling policy and parameters of a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_setschedparam(pthread_t thread, int policy,
                          const struct sched_param *param);
int pthread_getschedparam(pthread_t thread, int *restrict policy,
                          struct sched_param *restrict param);
```

DESCRIPTION

The **pthread_setschedparam**() function sets the scheduling policy and parameters of the thread *thread*.

policy specifies the new scheduling policy for *thread*. The supported values for *policy*, and their semantics, are described in *sched*(7).

The structure pointed to by *param* specifies the new scheduling parameters for *thread*. Scheduling parameters are maintained in the following structure:

```
struct sched_param {
    int sched_priority;     /* Scheduling priority */
};
```

As can be seen, only one scheduling parameter is supported. For details of the permitted ranges for scheduling priorities in each scheduling policy, see *sched*(7).

The **pthread_getschedparam**() function returns the scheduling policy and parameters of the thread *thread*, in the buffers pointed to by *policy* and *param*, respectively. The returned priority value is that set by the most recent **pthread_setschedparam**(), *pthread_setschedprio*(3), or *pthread_create*(3) call that affected *thread*. The returned priority does not reflect any temporary priority adjustments as a result of calls to any priority inheritance or priority ceiling functions (see, for example, *pthread_mutexattr_setprioceiling*(3) and *pthread_mutexattr_setprotocol*(3)).

RETURN VALUE

On success, these functions return 0; on error, they return a nonzero error number. If **pthread_setschedparam**() fails, the scheduling policy and parameters of *thread* are not changed.

ERRORS

Both of these functions can fail with the following error:

ESRCH
No thread with the ID *thread* could be found.

pthread_setschedparam() may additionally fail with the following errors:

EINVAL
policy is not a recognized policy, or *param* does not make sense for the *policy*.

EPERM
The caller does not have appropriate privileges to set the specified scheduling policy and parameters.

POSIX.1 also documents an **ENOTSUP** ("attempt was made to set the policy or scheduling parameters to an unsupported value") error for **pthread_setschedparam**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_setschedparam(), **pthread_getschedparam**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.0 POSIX.1-2001.

NOTES

For a description of the permissions required to, and the effect of, changing a thread's scheduling policy and priority, and details of the permitted ranges for priorities in each scheduling policy, see *sched*(7).

EXAMPLES

The program below demonstrates the use of **pthread_setschedparam**() and **pthread_getschedparam**(), as well as the use of a number of other scheduling-related pthreads functions.

In the following run, the main thread sets its scheduling policy to **SCHED_FIFO** with a priority of 10, and initializes a thread attributes object with a scheduling policy attribute of **SCHED_RR** and a scheduling priority attribute of 20. The program then sets (using *pthread_attr_setinheritsched*(3)) the inherit scheduler attribute of the thread attributes object to **PTHREAD_EXPLICIT_SCHED**, meaning that threads created using this attributes object should take their scheduling attributes from the thread attributes object. The program then creates a thread using the thread attributes object, and that thread displays its scheduling policy and priority.

```
$ su      # Need privilege to set real-time scheduling policies
Password:
# ./a.out -mf10 -ar20 -i e
Scheduler settings of main thread
    policy=SCHED_FIFO, priority=10

Scheduler settings in 'attr'
    policy=SCHED_RR, priority=20
    inheritsched is EXPLICIT

Scheduler attributes of new thread
    policy=SCHED_RR, priority=20
```

In the above output, one can see that the scheduling policy and priority were taken from the values specified in the thread attributes object.

The next run is the same as the previous, except that the inherit scheduler attribute is set to **PTHREAD_INHERIT_SCHED**, meaning that threads created using the thread attributes object should ignore the scheduling attributes specified in the attributes object and instead take their scheduling attributes from the creating thread.

```
# ./a.out -mf10 -ar20 -i i
Scheduler settings of main thread
    policy=SCHED_FIFO, priority=10

Scheduler settings in 'attr'
    policy=SCHED_RR, priority=20
    inheritsched is INHERIT

Scheduler attributes of new thread
    policy=SCHED_FIFO, priority=10
```

In the above output, one can see that the scheduling policy and priority were taken from the creating thread, rather than the thread attributes object.

Note that if we had omitted the *-i i* option, the output would have been the same, since **PTHREAD_INHERIT_SCHED** is the default for the inherit scheduler attribute.

NAME

pthread_setschedprio − set scheduling priority of a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_setschedprio(pthread_t *thread***, int** *prio***);**

DESCRIPTION

The **pthread_setschedprio**() function sets the scheduling priority of the thread *thread* to the value specified in *prio*. (By contrast *pthread_setschedparam*(3) changes both the scheduling policy and priority of a thread.)

RETURN VALUE

On success, this function returns 0; on error, it returns a nonzero error number. If **pthread_setschedprio**() fails, the scheduling priority of *thread* is not changed.

ERRORS

EINVAL

prio is not valid for the scheduling policy of the specified thread.

EPERM

The caller does not have appropriate privileges to set the specified priority.

ESRCH

No thread with the ID *thread* could be found.

POSIX.1 also documents an **ENOTSUP** ("attempt was made to set the priority to an unsupported value") error for *pthread_setschedparam*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_setschedprio()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.3.4. POSIX.1-2001.

NOTES

For a description of the permissions required to, and the effect of, changing a thread's scheduling priority, and details of the permitted ranges for priorities in each scheduling policy, see *sched*(7).

NAME

pthread_sigmask − examine and change mask of blocked signals

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <signal.h>

int pthread_sigmask(int *how***, const sigset_t ****set***, sigset_t ****oldset***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_sigmask():
_POSIX_C_SOURCE >= 199506L || _XOPEN_SOURCE >= 500

DESCRIPTION

The **pthread_sigmask**() function is just like *sigprocmask*(2), with the difference that its use in multi-threaded programs is explicitly specified by POSIX.1. Other differences are noted in this page.

For a description of the arguments and operation of this function, see *sigprocmask*(2).

RETURN VALUE

On success, **pthread_sigmask**() returns 0; on error, it returns an error number.

ERRORS

See *sigprocmask*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_sigmask()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

A new thread inherits a copy of its creator's signal mask.

The glibc **pthread_sigmask**() function silently ignores attempts to block the two real-time signals that are used internally by the NPTL threading implementation. See *nptl*(7) for details.

EXAMPLES

The program below blocks some signals in the main thread, and then creates a dedicated thread to fetch those signals via *sigwait*(3). The following shell session demonstrates its use:

```
$ ./a.out &
[1] 5423
$ kill -QUIT %1
Signal handling thread got signal 3
$ kill -USR1 %1
Signal handling thread got signal 10
$ kill -TERM %1
[1]+  Terminated              ./a.out
```

Program source

```
#include <errno.h>
#include <pthread.h>
#include <signal.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

/* Simple error handling functions */
```

```
#define handle_error_en(en, msg) \
        do { errno = en; perror(msg); exit(EXIT_FAILURE); } while (0)

static void *
sig_thread(void *arg)
{
    sigset_t *set = arg;
    int s, sig;

    for (;;) {
        s = sigwait(set, &sig);
        if (s != 0)
            handle_error_en(s, "sigwait");
        printf("Signal handling thread got signal %d\n", sig);
    }
}

int
main(void)
{
    pthread_t thread;
    sigset_t set;
    int s;

    /* Block SIGQUIT and SIGUSR1; other threads created by main()
       will inherit a copy of the signal mask. */

    sigemptyset(&set);
    sigaddset(&set, SIGQUIT);
    sigaddset(&set, SIGUSR1);
    s = pthread_sigmask(SIG_BLOCK, &set, NULL);
    if (s != 0)
        handle_error_en(s, "pthread_sigmask");

    s = pthread_create(&thread, NULL, &sig_thread, &set);
    if (s != 0)
        handle_error_en(s, "pthread_create");

    /* Main thread carries on to create other threads and/or do
       other work. */

    pause();            /* Dummy pause so we can test program */
}
```

NAME

pthread_sigqueue − queue a signal and data to a thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <signal.h>
#include <pthread.h>

int pthread_sigqueue(pthread_t thread, int sig,
                     const union sigval value);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_sigqueue():
_GNU_SOURCE

DESCRIPTION

The **pthread_sigqueue**() function performs a similar task to *sigqueue*(3), but, rather than sending a signal to a process, it sends a signal to a thread in the same process as the calling thread.

The *thread* argument is the ID of a thread in the same process as the caller. The *sig* argument specifies the signal to be sent. The *value* argument specifies data to accompany the signal; see *sigqueue*(3) for details.

RETURN VALUE

On success, **pthread_sigqueue**() returns 0; on error, it returns an error number.

ERRORS

EAGAIN
The limit of signals which may be queued has been reached. (See *signal*(7) for further information.)

EINVAL
sig was invalid.

ENOSYS
pthread_sigqueue() is not supported on this system.

ESRCH
thread is not valid.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_sigqueue()	Thread safety	MT-Safe

VERSIONS

The glibc implementation of **pthread_sigqueue**() gives an error (**EINVAL**) on attempts to send either of the real-time signals used internally by the NPTL threading implementation. See *nptl*(7) for details.

STANDARDS

GNU.

HISTORY

glibc 2.11.

SEE ALSO

NAME

pthread_spin_init, pthread_spin_destroy − initialize or destroy a spin lock

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <pthread.h>

int pthread_spin_init(pthread_spinlock_t *lock, int pshared);
int pthread_spin_destroy(pthread_spinlock_t *lock);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_spin_init(), **pthread_spin_destroy**():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

General note: Most programs should use mutexes instead of spin locks. Spin locks are primarily useful in conjunction with real-time scheduling policies. See NOTES.

The **pthread_spin_init**() function allocates any resources required for the use of the spin lock referred to by *lock* and initializes the lock to be in the unlocked state. The *pshared* argument must have one of the following values:

PTHREAD_PROCESS_PRIVATE
: The spin lock is to be operated on only by threads in the same process as the thread that calls **pthread_spin_init**(). (Attempting to share the spin lock between processes results in undefined behavior.)

PTHREAD_PROCESS_SHARED
: The spin lock may be operated on by any thread in any process that has access to the memory containing the lock (i.e., the lock may be in a shared memory object that is shared among multiple processes).

Calling **pthread_spin_init**() on a spin lock that has already been initialized results in undefined behavior.

The **pthread_spin_destroy**() function destroys a previously initialized spin lock, freeing any resources that were allocated for that lock. Destroying a spin lock that has not been previously been initialized or destroying a spin lock while another thread holds the lock results in undefined behavior.

Once a spin lock has been destroyed, performing any operation on the lock other than once more initializing it with **pthread_spin_init**() results in undefined behavior.

The result of performing operations such as *pthread_spin_lock*(3), *pthread_spin_unlock*(3), and **pthread_spin_destroy**() on *copies* of the object referred to by *lock* is undefined.

RETURN VALUE

On success, there functions return zero. On failure, they return an error number. In the event that **pthread_spin_init**() fails, the lock is not initialized.

ERRORS

pthread_spin_init() may fail with the following errors:

EAGAIN
: The system has insufficient resources to initialize a new spin lock.

ENOMEM
: Insufficient memory to initialize the spin lock.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2. POSIX.1-2001.

Support for process-shared spin locks is a POSIX option. The option is supported in the glibc implementation.

NOTES

Spin locks should be employed in conjunction with real-time scheduling policies (**SCHED_FIFO**, or possibly **SCHED_RR**). Use of spin locks with nondeterministic scheduling policies such as **SCHED_OTHER** probably indicates a design mistake. The problem is that if a thread operating under such a policy is scheduled off the CPU while it holds a spin lock, then other threads will waste time spinning on the lock until the lock holder is once more rescheduled and releases the lock.

If threads create a deadlock situation while employing spin locks, those threads will spin forever consuming CPU time.

User-space spin locks are *not* applicable as a general locking solution. They are, by definition, prone to priority inversion and unbounded spin times. A programmer using spin locks must be exceptionally careful not only in the code, but also in terms of system configuration, thread placement, and priority assignment.

SEE ALSO

pthread_mutex_init(3), *pthread_mutex_lock*(3), *pthread_spin_lock*(3), *pthread_spin_unlock*(3), *pthreads*(7)

NAME

pthread_spin_lock, pthread_spin_trylock, pthread_spin_unlock − lock and unlock a spin lock

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

int pthread_spin_lock(pthread_spinlock_t ****lock*);**
int pthread_spin_trylock(pthread_spinlock_t ****lock*);**
int pthread_spin_unlock(pthread_spinlock_t ****lock*);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

pthread_spin_lock(), **pthread_spin_trylock**():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **pthread_spin_lock**() function locks the spin lock referred to by *lock*. If the spin lock is currently unlocked, the calling thread acquires the lock immediately. If the spin lock is currently locked by another thread, the calling thread spins, testing the lock until it becomes available, at which point the calling thread acquires the lock.

Calling **pthread_spin_lock**() on a lock that is already held by the caller or a lock that has not been initialized with *pthread_spin_init*(3) results in undefined behavior.

The **pthread_spin_trylock**() function is like **pthread_spin_lock**(), except that if the spin lock referred to by *lock* is currently locked, then, instead of spinning, the call returns immediately with the error **EBUSY**.

The **pthread_spin_unlock**() function unlocks the spin lock referred to *lock*. If any threads are spinning on the lock, one of those threads will then acquire the lock.

Calling **pthread_spin_unlock**() on a lock that is not held by the caller results in undefined behavior.

RETURN VALUE

On success, these functions return zero. On failure, they return an error number.

ERRORS

pthread_spin_lock() may fail with the following errors:

EDEADLOCK
The system detected a deadlock condition.

pthread_spin_trylock() fails with the following errors:

EBUSY
The spin lock is currently locked by another thread.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2. POSIX.1-2001.

CAVEATS

Applying any of the functions described on this page to an uninitialized spin lock results in undefined behavior.

Carefully read NOTES in *pthread_spin_init*(3).

SEE ALSO

pthread_spin_destroy(3), *pthread_spin_init*(3), *pthreads*(7)

NAME

pthread_testcancel − request delivery of any pending cancelation request

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <pthread.h>

void pthread_testcancel(void);

DESCRIPTION

Calling **pthread_testcancel**() creates a cancelation point within the calling thread, so that a thread that is otherwise executing code that contains no cancelation points will respond to a cancelation request.

If cancelability is disabled (using *pthread_setcancelstate*(3)), or no cancelation request is pending, then a call to **pthread_testcancel**() has no effect.

RETURN VALUE

This function does not return a value. If the calling thread is canceled as a consequence of a call to this function, then the function does not return.

ERRORS

This function always succeeds.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_testcancel()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.0. POSIX.1-2001.

EXAMPLES

See *pthread_cleanup_push*(3).

SEE ALSO

pthread_cancel(3), *pthread_cleanup_push*(3), *pthread_setcancelstate*(3), *pthreads*(7)

NAME

pthread_tryjoin_np, pthread_timedjoin_np − try to join with a terminated thread

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

int pthread_tryjoin_np(pthread_t thread, void **retval);
int pthread_timedjoin_np(pthread_t thread, void **retval,
                         const struct timespec *abstime);
```

DESCRIPTION

These functions operate in the same way as *pthread_join*(3), except for the differences described on this page.

The **pthread_tryjoin_np**() function performs a nonblocking join with the thread *thread*, returning the exit status of the thread in **retval*. If *thread* has not yet terminated, then instead of blocking, as is done by *pthread_join*(3), the call returns an error.

The **pthread_timedjoin_np**() function performs a join-with-timeout. If *thread* has not yet terminated, then the call blocks until a maximum time, specified in *abstime*, measured against the **CLOCK_REALTIME** clock. If the timeout expires before *thread* terminates, the call returns an error. The *abstime* argument is a *timespec*(3) structure, specifying an absolute time measured since the Epoch (see *time*(2)).

RETURN VALUE

On success, these functions return 0; on error, they return an error number.

ERRORS

These functions can fail with the same errors as *pthread_join*(3). **pthread_tryjoin_np**() can in addition fail with the following error:

EBUSY
thread had not yet terminated at the time of the call.

pthread_timedjoin_np() can in addition fail with the following errors:

EINVAL
abstime value is invalid (*tv_sec* is less than 0 or *tv_nsec* is greater than 1e9).

ETIMEDOUT
The call timed out before *thread* terminated.

pthread_timedjoin_np() never returns the error **EINTR**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_tryjoin_np(), **pthread_timedjoin_np**()	Thread safety	MT-Safe

STANDARDS

GNU; hence the suffix "_np" (nonportable) in the names.

HISTORY

glibc 2.3.3.

BUGS

The **pthread_timedjoin_np**() function measures time by internally calculating a relative sleep interval that is then measured against the **CLOCK_MONOTONIC** clock instead of the **CLOCK_REALTIME** clock. Consequently, the timeout is unaffected by discontinuous changes to the **CLOCK_REALTIME** clock.

EXAMPLES

The following code waits to join for up to 5 seconds:

```
struct timespec ts;
int s;
```

```
        ...

        if (clock_gettime(CLOCK_REALTIME, &ts) == -1) {
            /* Handle error */
        }

        ts.tv_sec += 5;

        s = pthread_timedjoin_np(thread, NULL, &ts);
        if (s != 0) {
            /* Handle error */
        }
```

SEE ALSO

clock_gettime(2), *pthread_exit*(3), *pthread_join*(3), *timespec*(3), *pthreads*(7)

NAME

pthread_yield − yield the processor

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <pthread.h>

[[deprecated]] int pthread_yield(void);
```

DESCRIPTION

Note: This function is deprecated; see below.

pthread_yield() causes the calling thread to relinquish the CPU. The thread is placed at the end of the run queue for its static priority and another thread is scheduled to run. For further details, see *sched_yield*(2)

RETURN VALUE

On success, **pthread_yield**() returns 0; on error, it returns an error number.

ERRORS

On Linux, this call always succeeds (but portable and future-proof applications should nevertheless handle a possible error return).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
pthread_yield()	Thread safety	MT-Safe

VERSIONS

On Linux, this function is implemented as a call to *sched_yield*(2).

STANDARDS

None.

HISTORY

Deprecated since glibc 2.34. Use the standardized *sched_yield*(2) instead.

NOTES

pthread_yield() is intended for use with real-time scheduling policies (i.e., **SCHED_FIFO** or **SCHED_RR**). Use of **pthread_yield**() with nondeterministic scheduling policies such as **SCHED_OTHER** is unspecified and very likely means your application design is broken.

SEE ALSO

sched_yield(2), *pthreads*(7), *sched*(7)

NAME

ptsname, ptsname_r − get the name of the slave pseudoterminal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

char *ptsname(int fd);
int ptsname_r(int fd, char buf[.buflen], size_t buflen);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ptsname():
  Since glibc 2.24:
    _XOPEN_SOURCE >= 500
  glibc 2.23 and earlier:
    _XOPEN_SOURCE

ptsname_r():
  _GNU_SOURCE

DESCRIPTION

The **ptsname**() function returns the name of the slave pseudoterminal device corresponding to the master referred to by the file descriptor *fd*.

The **ptsname_r**() function is the reentrant equivalent of **ptsname**(). It returns the name of the slave pseudoterminal device as a null-terminated string in the buffer pointed to by *buf*. The *buflen* argument specifies the number of bytes available in *buf*.

RETURN VALUE

On success, **ptsname**() returns a pointer to a string in static storage which will be overwritten by subsequent calls. This pointer must not be freed. On failure, NULL is returned.

On success, **ptsname_r**() returns 0. On failure, an error number is returned to indicate the error.

ERRORS

EINVAL
: (**ptsname_r**() only) *buf* is NULL. (This error is returned only for glibc 2.25 and earlier.)

ENOTTY
: *fd* does not refer to a pseudoterminal master device.

ERANGE
: (**ptsname_r**() only) *buf* is too small.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ptsname()	Thread safety	MT-Unsafe race:ptsname
ptsname_r()	Thread safety	MT-Safe

VERSIONS

A version of **ptsname_r**() is documented on Tru64 and HP-UX, but on those implementations, −1 is returned on error, with *errno* set to indicate the error. Avoid using this function in portable programs.

STANDARDS

ptsname():
: POSIX.1-2008.

ptsname_r() is a Linux extension, that is proposed for inclusion in the next major revision of POSIX.1 (Issue 8).

HISTORY

ptsname():
: POSIX.1-2001. glibc 2.1.

ptsname() is part of the UNIX 98 pseudoterminal support (see *pts*(4)).

grantpt(3), *posix_openpt*(3), *ttyname*(3), *unlockpt*(3), *pts*(4), *pty*(7)

NAME

putenv − change or add an environment variable

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int putenv(char *string);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

putenv():

```
_XOPEN_SOURCE
    || /* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _SVID_SOURCE
```

DESCRIPTION

The **putenv**() function adds or changes the value of environment variables. The argument *string* is of the form *name=value*. If *name* does not already exist in the environment, then *string* is added to the environment. If *name* does exist, then the value of *name* in the environment is changed to *value*. The string pointed to by *string* becomes part of the environment, so altering the string changes the environment.

RETURN VALUE

The **putenv**() function returns zero on success. On failure, it returns a nonzero value, and *errno* is set to indicate the error.

ERRORS

ENOMEM
: Insufficient space to allocate new environment.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
putenv()	Thread safety	MT-Unsafe const:env

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr2, 4.3BSD-Reno.

The **putenv**() function is not required to be reentrant, and the one in glibc 2.0 is not, but the glibc 2.1 version is.

Since glibc 2.1.2, the glibc implementation conforms to SUSv2: the pointer *string* given to **putenv**() is used. In particular, this string becomes part of the environment; changing it later will change the environment. (Thus, it is an error to call **putenv**() with an automatic variable as the argument, then return from the calling function while *string* is still part of the environment.) However, from glibc 2.0 to glibc 2.1.1, it differs: a copy of the string is used. On the one hand this causes a memory leak, and on the other hand it violates SUSv2.

The 4.3BSD-Reno version, like glibc 2.0, uses a copy; this is fixed in all modern BSDs.

SUSv2 removes the *const* from the prototype, and so does glibc 2.1.3.

The GNU C library implementation provides a nonstandard extension. If *string* does not include an equal sign:

```
putenv("NAME");
```

then the named variable is removed from the caller's environment.

putgrent − write a group database entry to a file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#define _GNU_SOURCE /* See feature_test_macros(7) */
#include <grp.h>

int putgrent(const struct group *restrict *grp***, FILE *restrict** *stream***);**

DESCRIPTION

The **putgrent**() function is the counterpart for *fgetgrent*(3). The function writes the content of the provided *struct group* into the *stream*. The list of group members must be NULL-terminated or NULL-initialized.

The *struct group* is defined as follows:

```
struct group {
    char   *gr_name;      /* group name */
    char   *gr_passwd;    /* group password */
    gid_t   gr_gid;       /* group ID */
    char  **gr_mem;       /* group members */
};
```

RETURN VALUE

The function returns zero on success, and a nonzero value on error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
putgrent()	Thread safety	MT-Safe

STANDARDS

GNU.

fgetgrent(3), *getgrent*(3), *group*(5)

NAME

putpwent − write a password file entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <sys/types.h>
#include <pwd.h>

int putpwent(const struct passwd *restrict p, FILE *restrict stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

putpwent():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

The **putpwent**() function writes a password entry from the structure *p* in the file associated with *stream*.

The *passwd* structure is defined in <*pwd.h*> as follows:

```
struct passwd {
    char    *pw_name;       /* username */
    char    *pw_passwd;     /* user password */
    uid_t    pw_uid;        /* user ID */
    gid_t    pw_gid;        /* group ID */
    char    *pw_gecos;      /* real name */
    char    *pw_dir;        /* home directory */
    char    *pw_shell;      /* shell program */
};
```

RETURN VALUE

The **putpwent**() function returns 0 on success. On failure, it returns −1, and *errno* is set to indicate the error.

ERRORS

EINVAL
Invalid (NULL) argument given.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
putpwent()	Thread safety	MT-Safe locale

STANDARDS

NAME

fputc, fputs, putc, putchar, puts − output of characters and strings

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int fputc(int c, FILE *stream);
int putc(int c, FILE *stream);
int putchar(int c);

int fputs(const char *restrict s, FILE *restrict stream);
int puts(const char *s);
```

DESCRIPTION

fputc() writes the character *c*, cast to an *unsigned char*, to *stream*.

putc() is equivalent to **fputc**() except that it may be implemented as a macro which evaluates *stream* more than once.

putchar(*c***)** is equivalent to **putc(***c***,** *stdout***)**.

fputs() writes the string *s* to *stream*, without its terminating null byte ('\0').

puts() writes the string *s* and a trailing newline to *stdout*.

Calls to the functions described here can be mixed with each other and with calls to other output functions from the *stdio* library for the same output stream.

For nonlocking counterparts, see *unlocked_stdio*(3).

RETURN VALUE

fputc(), **putc**(), and **putchar**() return the character written as an *unsigned char* cast to an *int* or **EOF** on error.

puts() and **fputs**() return a nonnegative number on success, or **EOF** on error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
fputc(), **fputs**(), **putc**(), **putchar**(), **puts**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, C99.

BUGS

It is not advisable to mix calls to output functions from the *stdio* library with low-level calls to *write*(2) for the file descriptor associated with the same output stream; the results will be undefined and very probably not what you want.

SEE ALSO

write(2), *ferror*(3), *fgets*(3), *fopen*(3), *fputwc*(3), *fputws*(3), *fseek*(3), *fwrite*(3), *putwchar*(3), *scanf*(3), *unlocked_stdio*(3)

NAME

putwchar − write a wide character to standard output

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

wint_t putwchar(wchar_t *wc***);**

DESCRIPTION

The **putwchar**() function is the wide-character equivalent of the *putchar*(3) function. It writes the wide character *wc* to *stdout*. If *ferror(stdout)* becomes true, it returns **WEOF**. If a wide character conversion error occurs, it sets *errno* to **EILSEQ** and returns **WEOF**. Otherwise, it returns *wc*.

For a nonlocking counterpart, see *unlocked_stdio*(3).

RETURN VALUE

The **putwchar**() function returns *wc* if no error occurred, or **WEOF** to indicate an error.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
putwchar()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **putwchar**() depends on the **LC_CTYPE** category of the current locale.

It is reasonable to expect that **putwchar**() will actually write the multibyte sequence corresponding to the wide character *wc*.

SEE ALSO

fputwc(3), *unlocked_stdio*(3)

NAME

qecvt, qfcvt, qgcvt − convert a floating-point number to a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

[[deprecated]] char *qecvt(long double number, int ndigits,
                           int *restrict decpt, int *restrict sign);
[[deprecated]] char *qfcvt(long double number, int ndigits,
                           int *restrict decpt, int *restrict sign);
[[deprecated]] char *qgcvt(long double number, int ndigit, char *buf);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

qecvt(), **qfcvt**(), **qgcvt**():
Since glibc 2.19:
_DEFAULT_SOURCE
In glibc up to and including 2.19:
_SVID_SOURCE

DESCRIPTION

The functions **qecvt**(), **qfcvt**(), and **qgcvt**() are identical to *ecvt*(3), *fcvt*(3), and *gcvt*(3) respectively, except that they use a *long double* argument *number*. See *ecvt*(3) and *gcvt*(3).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

qsort, qsort_r − sort an array

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

void qsort(void base[.size * .nmemb], size_t nmemb, size_t size,
      int (*compar)(const void [.size], const void [.size]));
void qsort_r(void base[.size * .nmemb], size_t nmemb, size_t size,
      int (*compar)(const void [.size], const void [.size], void *),
      void *arg);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

qsort_r():
_GNU_SOURCE

DESCRIPTION

The **qsort**() function sorts an array with *nmemb* elements of size *size*. The *base* argument points to the start of the array.

The contents of the array are sorted in ascending order according to a comparison function pointed to by *compar*, which is called with two arguments that point to the objects being compared.

The comparison function must return an integer less than, equal to, or greater than zero if the first argument is considered to be respectively less than, equal to, or greater than the second. If two members compare as equal, their order in the sorted array is undefined.

The **qsort_r**() function is identical to **qsort**() except that the comparison function *compar* takes a third argument. A pointer is passed to the comparison function via *arg*. In this way, the comparison function does not need to use global variables to pass through arbitrary arguments, and is therefore reentrant and safe to use in threads.

RETURN VALUE

The **qsort**() and **qsort_r**() functions return no value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
qsort(), **qsort_r**()	Thread safety	MT-Safe

STANDARDS

qsort() C11, POSIX.1-2008.

HISTORY

qsort() POSIX.1-2001, C89, SVr4, 4.3BSD.

qsort_r()
glibc 2.8.

NOTES

To compare C strings, the comparison function can call *strcmp*(3), as shown in the example below.

EXAMPLES

For one example of use, see the example under *bsearch*(3).

Another example is the following program, which sorts the strings given in its command-line arguments:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

static int
cmpstringp(const void *p1, const void *p2)
{
```

```
        /* The actual arguments to this function are "pointers to
           pointers to char", but strcmp(3) arguments are "pointers
           to char", hence the following cast plus dereference. */

        return strcmp(*(const char **) p1, *(const char **) p2);
    }

    int
    main(int argc, char *argv[])
    {
        if (argc < 2) {
            fprintf(stderr, "Usage: %s <string>...\n", argv[0]);
            exit(EXIT_FAILURE);
        }

        qsort(&argv[1], argc - 1, sizeof(char *), cmpstringp);

        for (size_t j = 1; j < argc; j++)
            puts(argv[j]);
        exit(EXIT_SUCCESS);
    }
```

SEE ALSO

sort(1), *alphasort*(3), *strcmp*(3), *versionsort*(3)

NAME

raise − send a signal to the caller

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <signal.h>

int raise(int *sig***);**

DESCRIPTION

The **raise**() function sends a signal to the calling process or thread. In a single-threaded program it is equivalent to

```
kill(getpid(), sig);
```

In a multithreaded program it is equivalent to

```
pthread_kill(pthread_self(), sig);
```

If the signal causes a handler to be called, **raise**() will return only after the signal handler has returned.

RETURN VALUE

raise() returns 0 on success, and nonzero for failure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
raise()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89.

Since glibc 2.3.3, **raise**() is implemented by calling *tgkill*(2), if the kernel supports that system call. Older glibc versions implemented **raise**() using *kill*(2).

SEE ALSO

getpid(2), *kill*(2), *sigaction*(2), *signal*(2), *pthread_kill*(3), *signal*(7)

NAME

rand, rand_r, srand − pseudo-random number generator

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int rand(void);
void srand(unsigned int seed);

[[deprecated]] int rand_r(unsigned int *seedp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

rand_r():
Since glibc 2.24:
_POSIX_C_SOURCE >= 199506L
glibc 2.23 and earlier
_POSIX_C_SOURCE

DESCRIPTION

The **rand**() function returns a pseudo-random integer in the range 0 to **RAND_MAX** inclusive (i.e., the mathematical range [0, **RAND_MAX**]).

The **srand**() function sets its argument as the seed for a new sequence of pseudo-random integers to be returned by **rand**(). These sequences are repeatable by calling **srand**() with the same seed value.

If no seed value is provided, the **rand**() function is automatically seeded with a value of 1.

The function **rand**() is not reentrant, since it uses hidden state that is modified on each call. This might just be the seed value to be used by the next call, or it might be something more elaborate. In order to get reproducible behavior in a threaded application, this state must be made explicit; this can be done using the reentrant function **rand_r**().

Like **rand**(), **rand_r**() returns a pseudo-random integer in the range [0, **RAND_MAX**]. The *seedp* argument is a pointer to an *unsigned int* that is used to store state between calls. If **rand_r**() is called with the same initial value for the integer pointed to by *seedp*, and that value is not modified between calls, then the same pseudo-random sequence will result.

The value pointed to by the *seedp* argument of **rand_r**() provides only a very small amount of state, so this function will be a weak pseudo-random generator. Try *drand48_r*(3) instead.

RETURN VALUE

The **rand**() and **rand_r**() functions return a value between 0 and **RAND_MAX** (inclusive). The **srand**() function returns no value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
rand(), **rand_r**(), **srand**()	Thread safety	MT-Safe

VERSIONS

The versions of **rand**() and **srand**() in the Linux C Library use the same random number generator as *random*(3) and *srandom*(3), so the lower-order bits should be as random as the higher-order bits. However, on older **rand**() implementations, and on current implementations on different systems, the lower-order bits are much less random than the higher-order bits. Do not use this function in applications intended to be portable when good randomness is needed. (Use *random*(3) instead.)

STANDARDS

rand()
srand()
C11, POSIX.1-2008.

rand_r()
POSIX.1-2008.

HISTORY

rand()
srand()
SVr4, 4.3BSD, C89, POSIX.1-2001.

rand_r()
POSIX.1-2001. Obsolete in POSIX.1-2008.

EXAMPLES

POSIX.1-2001 gives the following example of an implementation of **rand**() and **srand**(), possibly useful when one needs the same sequence on two different machines.

```
static unsigned long next = 1;

/* RAND_MAX assumed to be 32767 */
int myrand(void) {
    next = next * 1103515245 + 12345;
    return((unsigned)(next/65536) % 32768);
}

void mysrand(unsigned int seed) {
    next = seed;
}
```

The following program can be used to display the pseudo-random sequence produced by **rand**() when given a particular seed. When the seed is *−1*, the program uses a random seed.

```
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
{
    int           r;
    unsigned int  seed, nloops;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <seed> <nloops>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    seed = atoi(argv[1]);
    nloops = atoi(argv[2]);

    if (seed == -1) {
        seed = arc4random();
        printf("seed: %u\n", seed);
    }

    srand(seed);
    for (unsigned int j = 0; j < nloops; j++) {
        r =  rand();
        printf("%d\n", r);
    }

    exit(EXIT_SUCCESS);
}
```

SEE ALSO

drand48(3), *random*(3)

NAME

random, srandom, initstate, setstate − random number generator

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

long random(void);
void srandom(unsigned int seed);

char *initstate(unsigned int seed, char state[.n], size_t n);
char *setstate(char *state);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

random(), **srandom**(), **initstate**(), **setstate**():

```
_XOPEN_SOURCE >= 500
    || /* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE
```

DESCRIPTION

The **random**() function uses a nonlinear additive feedback random number generator employing a default table of size 31 long integers to return successive pseudo-random numbers in the range from 0 to 2^31 − 1. The period of this random number generator is very large, approximately *16 * ((2^31) − 1)*.

The **srandom**() function sets its argument as the seed for a new sequence of pseudo-random integers to be returned by **random**(). These sequences are repeatable by calling **srandom**() with the same seed value. If no seed value is provided, the **random**() function is automatically seeded with a value of 1.

The **initstate**() function allows a state array *state* to be initialized for use by **random**(). The size of the state array *n* is used by **initstate**() to decide how sophisticated a random number generator it should use—the larger the state array, the better the random numbers will be. Current "optimal" values for the size of the state array *n* are 8, 32, 64, 128, and 256 bytes; other amounts will be rounded down to the nearest known amount. Using less than 8 bytes results in an error. *seed* is the seed for the initialization, which specifies a starting point for the random number sequence, and provides for restarting at the same point.

The **setstate**() function changes the state array used by the **random**() function. The state array *state* is used for random number generation until the next call to **initstate**() or **setstate**(). *state* must first have been initialized using **initstate**() or be the result of a previous call of **setstate**().

RETURN VALUE

The **random**() function returns a value between 0 and *(2^31) − 1*. The **srandom**() function returns no value.

The **initstate**() function returns a pointer to the previous state array. On failure, it returns NULL, and *errno* is set to indicate the error.

On success, **setstate**() returns a pointer to the previous state array. On failure, it returns NULL, and *errno* is set to indicate the error.

ERRORS

EINVAL
: The *state* argument given to **setstate**() was NULL.

EINVAL
: A state array of less than 8 bytes was specified to **initstate**().

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
random(), **srandom**(), **initstate**(), **setstate**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.3BSD.

NOTES

Random-number generation is a complex topic. *Numerical Recipes in C: The Art of Scientific Computing* (William H. Press, Brian P. Flannery, Saul A. Teukolsky, William T. Vetterling; New York: Cambridge University Press, 2007, 3rd ed.) provides an excellent discussion of practical random-number generation issues in Chapter 7 (Random Numbers).

For a more theoretical discussion which also covers many practical issues in depth, see Chapter 3 (Random Numbers) in Donald E. Knuth's *The Art of Computer Programming*, volume 2 (Seminumerical Algorithms), 2nd ed.; Reading, Massachusetts: Addison-Wesley Publishing Company, 1981.

CAVEATS

The **random**() function should not be used in multithreaded programs where reproducible behavior is required. Use *random_r*(3) for that purpose.

BUGS

According to POSIX, **initstate**() should return NULL on error. In the glibc implementation, *errno* is (as specified) set on error, but the function does not return NULL.

SEE ALSO

getrandom(2), *drand48*(3), *rand*(3), *random_r*(3), *srand*(3)

NAME

random_r, srandom_r, initstate_r, setstate_r − reentrant random number generator

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int random_r(struct random_data *restrict buf,
        int32_t *restrict result);
int srandom_r(unsigned int seed, struct random_data *buf);

int initstate_r(unsigned int seed, char statebuf[restrict .statelen],
        size_t statelen, struct random_data *restrict buf);
int setstate_r(char *restrict statebuf,
        struct random_data *restrict buf);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

random_r(), **srandom_r**(), **initstate_r**(), **setstate_r**():

```
/* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE
```

DESCRIPTION

These functions are the reentrant equivalents of the functions described in *random*(3). They are suitable for use in multithreaded programs where each thread needs to obtain an independent, reproducible sequence of random numbers.

The **random_r**() function is like *random*(3), except that instead of using state information maintained in a global variable, it uses the state information in the argument pointed to by *buf*, which must have been previously initialized by **initstate_r**(). The generated random number is returned in the argument *result*.

The **srandom_r**() function is like *srandom*(3), except that it initializes the seed for the random number generator whose state is maintained in the object pointed to by *buf*, which must have been previously initialized by **initstate_r**(), instead of the seed associated with the global state variable.

The **initstate_r**() function is like *initstate*(3) except that it initializes the state in the object pointed to by *buf*, rather than initializing the global state variable. Before calling this function, the *buf.state* field must be initialized to NULL. The **initstate_r**() function records a pointer to the *statebuf* argument inside the structure pointed to by *buf*. Thus, *statebuf* should not be deallocated so long as *buf* is still in use. (So, *statebuf* should typically be allocated as a static variable, or allocated on the heap using *malloc*(3) or similar.)

The **setstate_r**() function is like *setstate*(3) except that it modifies the state in the object pointed to by *buf*, rather than modifying the global state variable. *state* must first have been initialized using **initstate_r**() or be the result of a previous call of **setstate_r**().

RETURN VALUE

All of these functions return 0 on success. On error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EINVAL
: A state array of less than 8 bytes was specified to **initstate_r**().

EINVAL
: The *statebuf* or *buf* argument to **setstate_r**() was NULL.

EINVAL
: The *buf* or *result* argument to **random_r**() was NULL.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
random_r(), **srandom_r**(), **initstate_r**(), **setstate_r**()	Thread safety	MT-Safe race:buf

STANDARDS

GNU.

BUGS

The **initstate_r**() interface is confusing. It appears that the *random_data* type is intended to be opaque, but the implementation requires the user to either initialize the *buf.state* field to NULL or zero out the entire structure before the call.

         sa_family_t af);
int ruserok_af(const char *rhost, int superuser,
         const char *ruser, const char *luser,
         sa_family_t af);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

rcmd(), **rcmd_af**(), **rresvport**(), **rresvport_af**(), **iruserok**(), **iruserok_af**(), **ruserok**(), **ruserok_af**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The **rcmd**() function is used by the superuser to execute a command on a remote machine using an authentication scheme based on privileged port numbers. The **rresvport**() function returns a file descriptor to a socket with an address in the privileged port space. The **iruserok**() and **ruserok**() functions are used by servers to authenticate clients requesting service with **rcmd**(). All four functions are used by the *rshd*(8) server (among others).

rcmd()

The **rcmd**() function looks up the host **ahost* using *gethostbyname*(3), returning −1 if the host does not exist. Otherwise, **ahost* is set to the standard name of the host and a connection is established to a server residing at the well-known Internet port *inport*.

If the connection succeeds, a socket in the Internet domain of type **SOCK_STREAM** is returned to the caller, and given to the remote command as *stdin* and *stdout*. If *fd2p* is nonzero, then an auxiliary channel to a control process will be set up, and a file descriptor for it will be placed in **fd2p*. The control process will return diagnostic output from the command (unit 2) on this channel, and will also accept bytes on this channel as being UNIX signal numbers, to be forwarded to the process group of the command. If *fd2p* is 0, then the *stderr* (unit 2 of the remote command) will be made the same as the *stdout* and no provision is made for sending arbitrary signals to the remote process, although you may be able to get its attention by using out-of-band data.

The protocol is described in detail in *rshd*(8)

rresvport()
The **rresvport**() function is used to obtain a socket with a privileged port bound to it. This socket is suitable for use by **rcmd**() and several other functions. Privileged ports are those in the range 0 to 1023. Only a privileged process (on Linux, a process that has the **CAP_NET_BIND_SERVICE** capability in the user namespace governing its network namespace) is allowed to bind to a privileged port. In the glibc implementation, this function restricts its search to the ports from 512 to 1023. The *port* argument is value-result: the value it supplies to the call is used as the starting point for a circular search of the port range; on (successful) return, it contains the port number that was bound to.

iruserok() and ruserok()
The **iruserok**() and **ruserok**() functions take a remote host's IP address or name, respectively, two usernames and a flag indicating whether the local user's name is that of the superuser. Then, if the user is *not* the superuser, it checks the */etc/hosts.equiv* file. If that lookup is not done, or is unsuccessful, the *.rhosts* in the local user's home directory is checked to see if the request for service is allowed.

If this file does not exist, is not a regular file, is owned by anyone other than the user or the superuser, is writable by anyone other than the owner, or is hardlinked anywhere, the check automatically fails. Zero is returned if the machine name is listed in the *hosts.equiv* file, or the host and remote username are found in the *.rhosts* file; otherwise **iruserok**() and **ruserok**() return −1. If the local domain (as obtained from *gethostname*(2)) is the same as the remote domain, only the machine name need be specified.

If the IP address of the remote host is known, **iruserok**() should be used in preference to **ruserok**(), as it does not require trusting the DNS server for the remote host's domain.

***_af() variants**
All of the functions described above work with IPv4 (**AF_INET**) sockets. The "_af" variants take an extra argument that allows the socket address family to be specified. For these functions, the *af* argument can be specified as **AF_INET** or **AF_INET6**. In addition, **rcmd_af**() supports the use of **AF_UNSPEC**.

RETURN VALUE
The **rcmd**() function returns a valid socket descriptor on success. It returns −1 on error and prints a diagnostic message on the standard error.

The **rresvport**() function returns a valid, bound socket descriptor on success. On failure, it returns −1 and sets *errno* to indicate the error. The error code **EAGAIN** is overloaded to mean: "All network ports in use".

For information on the return from **ruserok**() and **iruserok**(), see above.

ATTRIBUTES
For an explanation of the terms used in this section, see *attributes*(7).

NAME

re_comp, re_exec − BSD regex functions

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _REGEX_RE_COMP
#include <sys/types.h>
#include <regex.h>

[[deprecated]] char *re_comp(const char *regex);
[[deprecated]] int re_exec(const char *string);
```

DESCRIPTION

re_comp() is used to compile the null-terminated regular expression pointed to by *regex*. The compiled pattern occupies a static area, the pattern buffer, which is overwritten by subsequent use of **re_comp**(). If *regex* is NULL, no operation is performed and the pattern buffer's contents are not altered.

re_exec() is used to assess whether the null-terminated string pointed to by *string* matches the previously compiled *regex*.

RETURN VALUE

re_comp() returns NULL on successful compilation of *regex* otherwise it returns a pointer to an appropriate error message.

re_exec() returns 1 for a successful match, zero for failure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
re_comp(), **re_exec**()	Thread safety	MT-Unsafe

STANDARDS

None.

HISTORY

4.3BSD.

These functions are obsolete; the functions documented in *regcomp*(3) should be used instead.

NAME

readdir − read a directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <dirent.h>

struct dirent *readdir(DIR ***dirp*);**

DESCRIPTION

The **readdir**() function returns a pointer to a *dirent* structure representing the next directory entry in the directory stream pointed to by *dirp*. It returns NULL on reaching the end of the directory stream or if an error occurred.

In the glibc implementation, the *dirent* structure is defined as follows:

```
struct dirent {
    ino_t          d_ino;       /* Inode number */
    off_t          d_off;       /* Not an offset; see below */
    unsigned short d_reclen;    /* Length of this record */
    unsigned char  d_type;      /* Type of file; not supported
                                   by all filesystem types */
    char           d_name[256]; /* Null-terminated filename */
};
```

The only fields in the *dirent* structure that are mandated by POSIX.1 are *d_name* and *d_ino*. The other fields are unstandardized, and not present on all systems; see NOTES below for some further details.

The fields of the *dirent* structure are as follows:

d_ino This is the inode number of the file.

d_off The value returned in *d_off* is the same as would be returned by calling *telldir*(3) at the current position in the directory stream. Be aware that despite its type and name, the *d_off* field is seldom any kind of directory offset on modern filesystems. Applications should treat this field as an opaque value, making no assumptions about its contents; see also *telldir*(3).

d_reclen
This is the size (in bytes) of the returned record. This may not match the size of the structure definition shown above; see NOTES.

d_type This field contains a value indicating the file type, making it possible to avoid the expense of calling *lstat*(2) if further actions depend on the type of the file.

When a suitable feature test macro is defined (**_DEFAULT_SOURCE** since glibc 2.19, or **_BSD_SOURCE** on glibc 2.19 and earlier), glibc defines the following macro constants for the value returned in *d_type*:

DT_BLK This is a block device.

DT_CHR This is a character device.

DT_DIR This is a directory.

DT_FIFO This is a named pipe (FIFO).

DT_LNK This is a symbolic link.

DT_REG This is a regular file.

DT_SOCK This is a UNIX domain socket.

DT_UNKNOWN
The file type could not be determined.

Currently, only some filesystems (among them: Btrfs, ext2, ext3, and ext4) have full support for returning the file type in *d_type*. All applications must properly handle a return of **DT_UNKNOWN**.

d_name
This field contains the null terminated filename. *See NOTES*.

The data returned by **readdir**() may be overwritten by subsequent calls to **readdir**() for the same directory stream.

RETURN VALUE

On success, **readdir**() returns a pointer to a *dirent* structure. (This structure may be statically allocated; do not attempt to *free*(3) it.)

If the end of the directory stream is reached, NULL is returned and *errno* is not changed. If an error occurs, NULL is returned and *errno* is set to indicate the error. To distinguish end of stream from an error, set *errno* to zero before calling **readdir**() and then check the value of *errno* if NULL is returned.

ERRORS

EBADF
Invalid directory stream descriptor *dirp*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
readdir()	Thread safety	MT-Unsafe race:dirstream

In the current POSIX.1 specification (POSIX.1-2008), **readdir**() is not required to be thread-safe. However, in modern implementations (including the glibc implementation), concurrent calls to **readdir**() that specify different directory streams are thread-safe. In cases where multiple threads must read from the same directory stream, using **readdir**() with external synchronization is still preferable to the use of the deprecated *readdir_r*(3) function. It is expected that a future version of POSIX.1 will require that **readdir**() be thread-safe when concurrently employed on different directory streams.

VERSIONS

Only the fields *d_name* and (as an XSI extension) *d_ino* are specified in POSIX.1. Other than Linux, the *d_type* field is available mainly only on BSD systems. The remaining fields are available on many, but not all systems. Under glibc, programs can check for the availability of the fields not defined in POSIX.1 by testing whether the macros **_DIRENT_HAVE_D_NAMLEN**, **_DIRENT_HAVE_D_RECLEN**, **_DIRENT_HAVE_D_OFF**, or **_DIRENT_HAVE_D_TYPE** are defined.

The d_name field

The *dirent* structure definition shown above is taken from the glibc headers, and shows the *d_name* field with a fixed size.

Warning: applications should avoid any dependence on the size of the *d_name* field. POSIX defines it as *char d_name[]*, a character array of unspecified size, with at most **NAME_MAX** characters preceding the terminating null byte ('\0').

POSIX.1 explicitly notes that this field should not be used as an lvalue. The standard also notes that the use of *sizeof(d_name)* is incorrect; use *strlen(d_name)* instead. (On some systems, this field is defined as *char d_name[1]*!) By implication, the use *sizeof(struct dirent)* to capture the size of the record including the size of *d_name* is also incorrect.

Note that while the call

```
fpathconf(fd, _PC_NAME_MAX)
```

returns the value 255 for most filesystems, on some filesystems (e.g., CIFS, Windows SMB servers), the null-terminated filename that is (correctly) returned in *d_name* can actually exceed this size. In such cases, the *d_reclen* field will contain a value that exceeds the size of the glibc *dirent* structure shown above.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

NOTES

A directory stream is opened using *opendir*(3).

The order in which filenames are read by successive calls to **readdir**() depends on the filesystem

implementation; it is unlikely that the names will be sorted in any fashion.

NAME

readdir_r − read a directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <dirent.h>

[[deprecated]] int readdir_r(DIR *restrict dirp,
                             struct dirent *restrict entry,
                             struct dirent **restrict result);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

readdir_r():
_POSIX_C_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

This function is deprecated; use *readdir*(3) instead.

The **readdir_r**() function was invented as a reentrant version of *readdir*(3). It reads the next directory entry from the directory stream *dirp*, and returns it in the caller-allocated buffer pointed to by *entry*. For details of the *dirent* structure, see *readdir*(3).

A pointer to the returned buffer is placed in **result*; if the end of the directory stream was encountered, then NULL is instead returned in **result*.

It is recommended that applications use *readdir*(3) instead of **readdir_r**(). Furthermore, since glibc 2.24, glibc deprecates **readdir_r**(). The reasons are as follows:

- On systems where **NAME_MAX** is undefined, calling **readdir_r**() may be unsafe because the interface does not allow the caller to specify the length of the buffer used for the returned directory entry.
- On some systems, **readdir_r**() can't read directory entries with very long names. When the glibc implementation encounters such a name, **readdir_r**() fails with the error **ENAMETOOLONG** *after the final directory entry has been read*. On some other systems, **readdir_r**() may return a success status, but the returned *d_name* field may not be null terminated or may be truncated.
- In the current POSIX.1 specification (POSIX.1-2008), *readdir*(3) is not required to be thread-safe. However, in modern implementations (including the glibc implementation), concurrent calls to *readdir*(3) that specify different directory streams are thread-safe. Therefore, the use of **readdir_r**() is generally unnecessary in multithreaded programs. In cases where multiple threads must read from the same directory stream, using *readdir*(3) with external synchronization is still preferable to the use of **readdir_r**(), for the reasons given in the points above.
- It is expected that a future version of POSIX.1 will make **readdir_r**() obsolete, and require that *readdir*(3) be thread-safe when concurrently employed on different directory streams.

RETURN VALUE

The **readdir_r**() function returns 0 on success. On error, it returns a positive error number (listed under ERRORS). If the end of the directory stream is reached, **readdir_r**() returns 0, and returns NULL in **result*.

ERRORS

EBADF
Invalid directory stream descriptor *dirp*.

ENAMETOOLONG
A directory entry whose name was too long to be read was encountered.

ATTRIBUTES

NAME

realpath − return the canonicalized absolute pathname

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <limits.h>
#include <stdlib.h>

char *realpath(const char *restrict path,
               char *restrict resolved_path);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

realpath():

```
_XOPEN_SOURCE >= 500
    || /* glibc >= 2.19: */ _DEFAULT_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE
```

DESCRIPTION

realpath() expands all symbolic links and resolves references to */./*, */../* and extra '/' characters in the null-terminated string named by *path* to produce a canonicalized absolute pathname. The resulting pathname is stored as a null-terminated string, up to a maximum of **PATH_MAX** bytes, in the buffer pointed to by *resolved_path*. The resulting path will have no symbolic link, */./* or */../* components.

If *resolved_path* is specified as NULL, then **realpath**() uses *malloc*(3) to allocate a buffer of up to **PATH_MAX** bytes to hold the resolved pathname, and returns a pointer to this buffer. The caller should deallocate this buffer using *free*(3).

RETURN VALUE

If there is no error, **realpath**() returns a pointer to the *resolved_path*.

Otherwise, it returns NULL, the contents of the array *resolved_path* are undefined, and *errno* is set to indicate the error.

ERRORS

EACCES
: Read or search permission was denied for a component of the path prefix.

EINVAL
: *path* is NULL. (Before glibc 2.3, this error is also returned if *resolved_path* is NULL.)

EIO An I/O error occurred while reading from the filesystem.

ELOOP
: Too many symbolic links were encountered in translating the pathname.

ENAMETOOLONG
: A component of a pathname exceeded **NAME_MAX** characters, or an entire pathname exceeded **PATH_MAX** characters.

ENOENT
: The named file does not exist.

ENOMEM
: Out of memory.

ENOTDIR
: A component of the path prefix is not a directory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
realpath()	Thread safety	MT-Safe

VERSIONS

GNU extensions

If the call fails with either **EACCES** or **ENOENT** and *resolved_path* is not NULL, then the prefix of *path* that is not readable or does not exist is returned in *resolved_path*.

STANDARDS

POSIX.1-2008.

HISTORY

4.4BSD, POSIX.1-2001, Solaris.

POSIX.1-2001 says that the behavior if *resolved_path* is NULL is implementation-defined. POSIX.1-2008 specifies the behavior described in this page.

In 4.4BSD and Solaris, the limit on the pathname length is **MAXPATHLEN** (found in <*sys/param.h*>). SUSv2 prescribes **PATH_MAX** and **NAME_MAX**, as found in <*limits.h*> or provided by the *pathconf*(3) function. A typical source fragment would be

```
#ifdef PATH_MAX
  path_max = PATH_MAX;
#else
  path_max = pathconf(path, _PC_PATH_MAX);
  if (path_max <= 0)
    path_max = 4096;
#endif
```

(But see the BUGS section.)

BUGS

The POSIX.1-2001 standard version of this function is broken by design, since it is impossible to determine a suitable size for the output buffer, *resolved_path*. According to POSIX.1-2001 a buffer of size **PATH_MAX** suffices, but **PATH_MAX** need not be a defined constant, and may have to be obtained using *pathconf*(3). And asking *pathconf*(3) does not really help, since, on the one hand POSIX warns that the result of *pathconf*(3) may be huge and unsuitable for mallocing memory, and on the other hand *pathconf*(3) may return −1 to signify that **PATH_MAX** is not bounded. The *resolved_path* == *NULL* feature, not standardized in POSIX.1-2001, but standardized in POSIX.1-2008, allows this design problem to be avoided.

NAME

recno − record number database access method

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/types.h>
#include <db.h>

DESCRIPTION

Note well: This page documents interfaces provided up until glibc 2.1. Since glibc 2.2, glibc no longer provides these interfaces. Probably, you are looking for the APIs provided by the *libdb* library instead.

The routine *dbopen*(3) is the library interface to database files. One of the supported file formats is record number files. The general description of the database access methods is in *dbopen*(3), this manual page describes only the recno-specific information.

The record number data structure is either variable or fixed-length records stored in a flat-file format, accessed by the logical record number. The existence of record number five implies the existence of records one through four, and the deletion of record number one causes record number five to be renumbered to record number four, as well as the cursor, if positioned after record number one, to shift down one record.

The recno access-method-specific data structure provided to *dbopen*(3) is defined in the <*db.h*> include file as follows:

```
typedef struct {
    unsigned long flags;
    unsigned int  cachesize;
    unsigned int  psize;
    int           lorder;
    size_t        reclen;
    unsigned char bval;
    char         *bfname;
} RECNOINFO;
```

The elements of this structure are defined as follows:

flags The flag value is specified by ORing any of the following values:

R_FIXEDLEN
The records are fixed-length, not byte delimited. The structure element *reclen* specifies the length of the record, and the structure element *bval* is used as the pad character. Any records, inserted into the database, that are less than *reclen* bytes long are automatically padded.

R_NOKEY
In the interface specified by *dbopen*(3), the sequential record retrieval fills in both the caller's key and data structures. If the **R_NOKEY** flag is specified, the *cursor* routines are not required to fill in the key structure. This permits applications to retrieve records at the end of files without reading all of the intervening records.

R_SNAPSHOT
This flag requires that a snapshot of the file be taken when *dbopen*(3) is called, instead of permitting any unmodified records to be read from the original file.

cachesize
A suggested maximum size, in bytes, of the memory cache. This value is **only** advisory, and the access method will allocate more memory rather than fail. If *cachesize* is 0 (no size is specified), a default cache is used.

psize The recno access method stores the in-memory copies of its records in a btree. This value is the size (in bytes) of the pages used for nodes in that tree. If *psize* is 0 (no page size is specified), a page size is chosen based on the underlying filesystem I/O block size. See *btree*(3) for more information.

lorder The byte order for integers in the stored database metadata. The number should represent the order as an integer; for example, big endian order would be the number 4,321. If *lorder* is 0 (no order is specified), the current host order is used.

reclen The length of a fixed-length record.

bval The delimiting byte to be used to mark the end of a record for variable-length records, and the pad character for fixed-length records. If no value is specified, newlines ("\n") are used to mark the end of variable-length records and fixed-length records are padded with spaces.

bfname The recno access method stores the in-memory copies of its records in a btree. If *bfname* is non-NULL, it specifies the name of the btree file, as if specified as the filename for a *dbopen*(3) of a btree file.

The data part of the key/data pair used by the *recno* access method is the same as other access methods. The key is different. The *data* field of the key should be a pointer to a memory location of type *recno_t*, as defined in the <*db.h*> include file. This type is normally the largest unsigned integral type available to the implementation. The *size* field of the key should be the size of that type.

Because there can be no metadata associated with the underlying recno access method files, any changes made to the default values (e.g., fixed record length or byte separator value) must be explicitly specified each time the file is opened.

In the interface specified by *dbopen*(3), using the *put* interface to create a new record will cause the creation of multiple, empty records if the record number is more than one greater than the largest record currently in the database.

ERRORS

The *recno* access method routines may fail and set *errno* for any of the errors specified for the library routine *dbopen*(3) or the following:

EINVAL
An attempt was made to add a record to a fixed-length database that was too large to fit.

BUGS

Only big and little endian byte order is supported.

NAME

regcomp, regexec, regerror, regfree − POSIX regex functions

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <regex.h>

int regcomp(regex_t *restrict preg, const char *restrict regex,
        int cflags);
int regexec(const regex_t *restrict preg, const char *restrict string,
        size_t nmatch, regmatch_t pmatch[_Nullable restrict .nmatch],
        int eflags);

size_t regerror(int errcode, const regex_t *_Nullable restrict preg,
        char errbuf[_Nullable restrict .errbuf_size],
        size_t errbuf_size);
void regfree(regex_t *preg);

typedef struct {
   size_t    re_nsub;
} regex_t;

typedef struct {
   regoff_t  rm_so;
   regoff_t  rm_eo;
} regmatch_t;

typedef /* ... */  regoff_t;
```

DESCRIPTION

Compilation

regcomp() is used to compile a regular expression into a form that is suitable for subsequent **regexec**() searches.

On success, the pattern buffer at **preg* is initialized. *regex* is a null-terminated string. The locale must be the same when running **regexec**().

After **regcomp**() succeeds, *preg->re_nsub* holds the number of subexpressions in *regex*. Thus, a value of *preg->re_nsub* + 1 passed as *nmatch* to **regexec**() is sufficient to capture all matches.

cflags is the bitwise OR of zero or more of the following:

REG_EXTENDED
: Use POSIX Extended Regular Expression syntax when interpreting *regex*. If not set, POSIX Basic Regular Expression syntax is used.

REG_ICASE
: Do not differentiate case. Subsequent **regexec**() searches using this pattern buffer will be case insensitive.

REG_NOSUB
: Report only overall success. **regexec**() will use only *pmatch* for **REG_STARTEND**, ignoring *nmatch*.

REG_NEWLINE
: Match-any-character operators don't match a newline.

  A nonmatching list (**[^...]**) not containing a newline does not match a newline.

  Match-beginning-of-line operator (^) matches the empty string immediately after a newline, regardless of whether *eflags*, the execution flags of **regexec**(), contains **REG_NOTBOL**.

  Match-end-of-line operator (**$**) matches the empty string immediately before a newline, regardless of whether *eflags* contains **REG_NOTEOL**.

Matching

regexec() is used to match a null-terminated string against the compiled pattern buffer in **preg*, which must have been initialised with **regexec**(). *eflags* is the bitwise OR of zero or more of the following

flags:

REG_NOTBOL
The match-beginning-of-line operator always fails to match (but see the compilation flag **REG_NEWLINE** above). This flag may be used when different portions of a string are passed to **regexec**() and the beginning of the string should not be interpreted as the beginning of the line.

REG_NOTEOL
The match-end-of-line operator always fails to match (but see the compilation flag **REG_NEWLINE** above).

REG_STARTEND
Match [*string* + *pmatch[0].rm_so*, *string* + *pmatch[0].rm_eo*) instead of [*string*, *string* + *strlen(string)*). This allows matching embedded NUL bytes and avoids a *strlen*(3) on known-length strings. If any matches are returned (**REG_NOSUB** wasn't passed to **regcomp**(), the match succeeded, and *nmatch* > 0), they overwrite *pmatch* as usual, and the match offsets remain relative to *string* (not *string* + *pmatch[0].rm_so*). This flag is a BSD extension, not present in POSIX.

Match offsets
Unless **REG_NOSUB** was passed to **regcomp**(), it is possible to obtain the locations of matches within *string*: **regexec**() fills *nmatch* elements of *pmatch* with results: *pmatch[0]* corresponds to the entire match, *pmatch[1]* to the first subexpression, etc. If there were more matches than *nmatch*, they are discarded; if fewer, unused elements of *pmatch* are filled with **-1**s.

Each returned valid (non-**−1**) match corresponds to the range [*string* + *rm_so*, *string* + *rm_eo*).

regoff_t is a signed integer type capable of storing the largest value that can be stored in either an *ptrdiff_t* type or a *ssize_t* type.

Error reporting
regerror() is used to turn the error codes that can be returned by both **regcomp**() and **regexec**() into error message strings.

If *preg* isn't a null pointer, *errcode* must be the latest error returned from an operation on *preg*.

If *errbuf_size* isn't 0, up to *errbuf_size* bytes are copied to *errbuf*; the error string is always null-terminated, and truncated to fit.

Freeing
regfree() deinitializes the pattern buffer at **preg*, freeing any associated memory; **preg* must have been initialized via **regcomp**().

RETURN VALUE

regcomp() returns zero for a successful compilation or an error code for failure.

regexec() returns zero for a successful match or **REG_NOMATCH** for failure.

regerror() returns the size of the buffer required to hold the string.

ERRORS

The following errors can be returned by **regcomp**():

REG_BADBR
Invalid use of back reference operator.

REG_BADPAT
Invalid use of pattern operators such as group or list.

REG_BADRPT
Invalid use of repetition operators such as using '*' as the first character.

REG_EBRACE
Un-matched brace interval operators.

REG_EBRACK
Un-matched bracket list operators.

REG_ECOLLATE
Invalid collating element.

REG_ECTYPE
Unknown character class name.

REG_EEND
Nonspecific error. This is not defined by POSIX.

REG_EESCAPE
Trailing backslash.

REG_EPAREN
Un-matched parenthesis group operators.

REG_ERANGE
Invalid use of the range operator; for example, the ending point of the range occurs prior to the starting point.

REG_ESIZE
Compiled regular expression requires a pattern buffer larger than 64 kB. This is not defined by POSIX.

REG_ESPACE
The regex routines ran out of memory.

REG_ESUBREG
Invalid back reference to a subexpression.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
regcomp(), **regexec**()	Thread safety	MT-Safe locale
regerror()	Thread safety	MT-Safe env
regfree()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

Prior to POSIX.1-2008, *regoff_t* was required to be capable of storing the largest value that can be stored in either an *off_t* type or a *ssize_t* type.

CAVEATS

re_nsub is only required to be initialized if **REG_NOSUB** wasn't specified, but all known implementations initialize it regardless.

Both *regex_t* and *regmatch_t* may (and do) have more members, in any order. Always reference them by name.

EXAMPLES

```
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#include <regex.h>

#define ARRAY_SIZE(arr) (sizeof((arr)) / sizeof((arr)[0]))

static const char *const str =
        "1) John Driverhacker;\n2) John Doe;\n3) John Foo;\n";
static const char *const re = "John.*o";

int main(void)
{
    static const char *s = str;
```

```
        regex_t     regex;
        regmatch_t  pmatch[1];
        regoff_t    off, len;

        if (regcomp(&regex, re, REG_NEWLINE))
            exit(EXIT_FAILURE);

        printf("String = \"%s\"\n", str);
        printf("Matches:\n");

        for (unsigned int i = 0; ; i++) {
            if (regexec(&regex, s, ARRAY_SIZE(pmatch), pmatch, 0))
                break;

            off = pmatch[0].rm_so + (s - str);
            len = pmatch[0].rm_eo - pmatch[0].rm_so;
            printf("#%zu:\n", i);
            printf("offset = %jd; length = %jd\n", (intmax_t) off,
                    (intmax_t) len);
            printf("substring = \"%.*s\"\n", len, s + pmatch[0].rm_so);

            s += pmatch[0].rm_eo;
        }

        exit(EXIT_SUCCESS);
    }
```

NAME

drem, dremf, dreml, remainder, remainderf, remainderl − floating-point remainder function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double remainder(double x, double y);
float remainderf(float x, float y);
long double remainderl(long double x, long double y);

/* Obsolete synonyms */
[[deprecated]] double drem(double x, double y);
[[deprecated]] float dremf(float x, float y);
[[deprecated]] long double dreml(long double x, long double y);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

remainder():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

remainderf(), **remainderl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

drem(), **dremf**(), **dreml**():
/* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions compute the remainder of dividing *x* by *y*. The return value is *x*−*n***y*, where *n* is the value *x* / *y*, rounded to the nearest integer. If the absolute value of *x*−*n***y* is 0.5, *n* is chosen to be even.

These functions are unaffected by the current rounding mode (see *fenv*(3)).

The **drem**() function does precisely the same thing.

RETURN VALUE

On success, these functions return the floating-point remainder, *x*−*n***y*. If the return value is 0, it has the sign of *x*.

If *x* or *y* is a NaN, a NaN is returned.

If *x* is an infinity, and *y* is not a NaN, a domain error occurs, and a NaN is returned.

If *y* is zero, and *x* is not a NaN, a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity and *y* is not a NaN
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

  These functions do not set *errno* for this case.

Domain error: *y* is zero
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
drem(), **dremf**(), **dreml**(), **remainder**(), **remainderf**(), **remainderl**()	Thread safety	MT-Safe

STANDARDS

remainder()
remainderf()
remainderl()
C11, POSIX.1-2008.

drem()
dremf()
dreml()
None.

HISTORY

remainder()
remainderf()
remainderl()
C99, POSIX.1-2001.

drem() 4.3BSD.

dremf()
dreml()
Tru64, glibc2.

BUGS

Before glibc 2.15, the call

```
remainder(nan(""), 0);
```

returned a NaN, as expected, but wrongly caused a domain error. Since glibc 2.15, a silent NaN (i.e., no domain error) is returned.

Before glibc 2.15, *errno* was not set to **EDOM** for the domain error that occurs when *x* is an infinity and *y* is not a NaN.

EXAMPLES

The call "remainder(29.0, 3.0)" returns −1.

SEE ALSO

div(3), *fmod*(3), *remquo*(3)

NAME

remove − remove a file or directory

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

int remove(const char ****pathname*);**

DESCRIPTION

remove() deletes a name from the filesystem. It calls *unlink*(2) for files, and *rmdir*(2) for directories.

If the removed name was the last link to a file and no processes have the file open, the file is deleted and the space it was using is made available for reuse.

If the name was the last link to a file, but any processes still have the file open, the file will remain in existence until the last file descriptor referring to it is closed.

If the name referred to a symbolic link, the link is removed.

If the name referred to a socket, FIFO, or device, the name is removed, but processes which have the object open may continue to use it.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

The errors that occur are those for *unlink*(2) and *rmdir*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
remove()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, 4.3BSD.

BUGS

Infelicities in the protocol underlying NFS can cause the unexpected disappearance of files which are still being used.

NAME

remquo, remquof, remquol − remainder and part of quotient

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double remquo(double x, double y, int *quo);
float remquof(float x, float y, int *quo);
long double remquol(long double x, long double y, int *quo);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

remquo(), **remquof**(), **remquol**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions compute the remainder and part of the quotient upon division of *x* by *y*. A few bits of the quotient are stored via the *quo* pointer. The remainder is returned as the function result.

The value of the remainder is the same as that computed by the *remainder*(3) function.

The value stored via the *quo* pointer has the sign of *x / y* and agrees with the quotient in at least the low order 3 bits.

For example, *remquo(29.0, 3.0)* returns −1.0 and might store 2. Note that the actual quotient might not fit in an integer.

RETURN VALUE

On success, these functions return the same value as the analogous functions described in *remainder*(3).

If *x* or *y* is a NaN, a NaN is returned.

If *x* is an infinity, and *y* is not a NaN, a domain error occurs, and a NaN is returned.

If *y* is zero, and *x* is not a NaN, a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity or *y* is 0, and the other argument is not a NaN
An invalid floating-point exception (**FE_INVALID**) is raised.

These functions do not set *errno*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

[[deprecated]]
int res_send(const unsigned char *msg***[.***msglen***], int** *msglen***,**
unsigned char *answer***[.***anslen***], int** *anslen***);**

DESCRIPTION

Note: This page is incomplete (various resolver functions provided by glibc are not described) and likely out of date.

The functions described below make queries to and interpret the responses from Internet domain name servers.

The API consists of a set of more modern, reentrant functions and an older set of nonreentrant functions that have been superseded. The traditional resolver interfaces such as **res_init**() and **res_query**() use some static (global) state stored in the *_res* structure, rendering these functions non-thread-safe. BIND 8.2 introduced a set of new interfaces **res_ninit**(), **res_nquery**(), and so on, which take a *res_state* as their first argument, so you can use a per-thread resolver state.

The **res_ninit**() and **res_init**() functions read the configuration files (see *resolv.conf*(5)) to get the default domain name and name server address(es). If no server is given, the local host is tried. If no domain is given, that associated with the local host is used. It can be overridden with the environment variable **LOCALDOMAIN**. **res_ninit**() or **res_init**() is normally executed by the first call to one of the other functions. Every call to **res_ninit**() requires a corresponding call to **res_nclose**() to free memory allocated by **res_ninit**() and subsequent calls to **res_nquery**().

The **res_nquery**() and **res_query**() functions query the name server for the fully qualified domain name *name* of specified *type* and *class*. The reply is left in the buffer *answer* of length *anslen* supplied by the caller.

The **res_nsearch**() and **res_search**() functions make a query and waits for the response like **res_nquery**() and **res_query**(), but in addition they implement the default and search rules controlled by **RES_DEFNAMES** and **RES_DNSRCH** (see description of *_res* options below).

The **res_nquerydomain**() and **res_querydomain**() functions make a query using *res_nquery*()/*res_query*() on the concatenation of *name* and *domain*.

The following functions are lower-level routines used by *res_nquery*()/*res_query*()

The **res_nmkquery**() and **res_mkquery**() functions construct a query message in *buf* of length *buflen* for the domain name *dname*. The query type *op* is one of the following (typically **QUERY**):

QUERY
Standard query.

IQUERY
Inverse query. This option was removed in glibc 2.26, since it has not been supported by DNS servers for a very long time.

NS_NOTIFY_OP
Notify secondary of SOA (Start of Authority) change.

newrr is currently unused.

The **res_nsend**() and **res_send**() function send a preformatted query given in *msg* of length *msglen* and returns the answer in *answer* which is of length *anslen*. They will call *res_ninit*()/*res_init*() if it has not already been called.

The **dn_comp**() function compresses the domain name *exp_dn* and stores it in the buffer *comp_dn* of length *length*. The compression uses an array of pointers *dnptrs* to previously compressed names in the current message. The first pointer points to the beginning of the message and the list ends with NULL. The limit of the array is specified by *lastdnptr*. If *dnptr* is NULL, domain names are not compressed. If *lastdnptr* is NULL, the list of labels is not updated.

The **dn_expand**() function expands the compressed domain name *comp_dn* to a full domain name,

which is placed in the buffer *exp_dn* of size *length*. The compressed name is contained in a query or reply message, and *msg* points to the beginning of the message.

The resolver routines use configuration and state information contained in a *__res_state* structure (either passed as the *statep* argument, or in the global variable *_res*, in the case of the older nonreentrant functions). The only field of this structure that is normally manipulated by the user is the *options* field. This field can contain the bitwise "OR" of the following options:

RES_INIT
: True if **res_ninit**() or **res_init**() has been called.

RES_DEBUG
: Print debugging messages. This option is available only if glibc was built with debugging enabled, which is not the default.

RES_AAONLY (unimplemented; deprecated in glibc 2.25)
: Accept authoritative answers only. **res_send**() continues until it finds an authoritative answer or returns an error. This option was present but unimplemented until glibc 2.24; since glibc 2.25, it is deprecated, and its usage produces a warning.

RES_USEVC
: Use TCP connections for queries rather than UDP datagrams.

RES_PRIMARY (unimplemented; deprecated in glibc 2.25)
: Query primary domain name server only. This option was present but unimplemented until glibc 2.24; since glibc 2.25, it is deprecated, and its usage produces a warning.

RES_IGNTC
: Ignore truncation errors. Don't retry with TCP.

RES_RECURSE
: Set the recursion desired bit in queries. Recursion is carried out by the domain name server, not by **res_send**(). [Enabled by default].

RES_DEFNAMES
: If set, **res_search**() will append the default domain name to single component names—that is, those that do not contain a dot. [Enabled by default].

RES_STAYOPEN
: Used with **RES_USEVC** to keep the TCP connection open between queries.

RES_DNSRCH
: If set, **res_search**() will search for hostnames in the current domain and in parent domains. This option is used by *gethostbyname*(3). [Enabled by default].

RES_INSECURE1
: Accept a response from a wrong server. This can be used to detect potential security hazards, but you need to compile glibc with debugging enabled and use **RES_DEBUG** option (for debug purpose only).

RES_INSECURE2
: Accept a response which contains a wrong query. This can be used to detect potential security hazards, but you need to compile glibc with debugging enabled and use **RES_DEBUG** option (for debug purpose only).

RES_NOALIASES
: Disable usage of **HOSTALIASES** environment variable.

RES_USE_INET6
: Try an AAAA query before an A query inside the *gethostbyname*(3) function, and map IPv4 responses in IPv6 "tunneled form" if no AAAA records are found but an A record set exists. Since glibc 2.25, this option is deprecated, and its usage produces a warning; applications should use *getaddrinfo*(3), rather than *gethostbyname*(3).

RES_ROTATE
: Causes round-robin selection of name servers from among those listed. This has the effect of spreading the query load among all listed servers, rather than having all clients try the first listed server first every time.

RES_NOCHECKNAME (unimplemented; deprecated in glibc 2.25)
Disable the modern BIND checking of incoming hostnames and mail names for invalid characters such as underscore (_), non-ASCII, or control characters. This option was present until glibc 2.24; since glibc 2.25, it is deprecated, and its usage produces a warning.

RES_KEEPTSIG (unimplemented; deprecated in glibc 2.25)
Do not strip TSIG records. This option was present but unimplemented until glibc 2.24; since glibc 2.25, it is deprecated, and its usage produces a warning.

RES_BLAST (unimplemented; deprecated in glibc 2.25)
Send each query simultaneously and recursively to all servers. This option was present but unimplemented until glibc 2.24; since glibc 2.25, it is deprecated, and its usage produces a warning.

RES_USEBSTRING (glibc 2.3.4 to glibc 2.24)
Make reverse IPv6 lookups using the bit-label format described in RFC 2673; if this option is not set (which is the default), then nibble format is used. This option was removed in glibc 2.25, since it relied on a backward-incompatible DNS extension that was never deployed on the Internet.

RES_NOIP6DOTINT (glibc 2.24 and earlier)
Use *ip6.arpa* zone in IPv6 reverse lookup instead of *ip6.int*, which is deprecated since glibc 2.3.4. This option is present up to and including glibc 2.24, where it is enabled by default. In glibc 2.25, this option was removed.

RES_USE_EDNS0 (since glibc 2.6)
Enables support for the DNS extensions (EDNS0) described in RFC 2671.

RES_SNGLKUP (since glibc 2.10)
By default, glibc performs IPv4 and IPv6 lookups in parallel since glibc 2.9. Some appliance DNS servers cannot handle these queries properly and make the requests time out. This option disables the behavior and makes glibc perform the IPv6 and IPv4 requests sequentially (at the cost of some slowdown of the resolving process).

RES_SNGLKUPREOP
When **RES_SNGLKUP** option is enabled, opens a new socket for the each request.

RES_USE_DNSSEC
Use DNSSEC with OK bit in OPT record. This option implies **RES_USE_EDNS0**.

RES_NOTLDQUERY
Do not look up unqualified name as a top-level domain (TLD).

RES_DEFAULT
Default option which implies: **RES_RECURSE**, **RES_DEFNAMES**, **RES_DNSRCH**, and **RES_NOIP6DOTINT**.

RETURN VALUE

The **res_ninit**() and **res_init**() functions return 0 on success, or −1 if an error occurs.

The **res_nquery**(), **res_query**(), **res_nsearch**(), **res_search**(), **res_nquerydomain**(), **res_querydomain**(), **res_nmkquery**(), **res_mkquery**(), **res_nsend**(), and **res_send**() functions return the length of the response, or −1 if an error occurs.

The **dn_comp**() and **dn_expand**() functions return the length of the compressed name, or −1 if an error occurs.

In the case of an error return from **res_nquery**(), **res_query**(), **res_nsearch**(), **res_search**(), **res_nquerydomain**(), or **res_querydomain**(), the global variable *h_errno* (see *gethostbyname*(3)) can be consulted to determine the cause of the error.

NAME

rexec, rexec_af − return stream to a remote command

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

[[deprecated]]
int rexec(char **restrict ahost, int inport,
          const char *restrict user, const char *restrict passwd,
          const char *restrict cmd, int *restrict fd2p);

[[deprecated]]
int rexec_af(char **restrict ahost, int inport,
          const char *restrict user, const char *restrict passwd,
          const char *restrict cmd, int *restrict fd2p,
          sa_family_t af);
```

rexec(), **rexec_af**():

Since glibc 2.19:

_DEFAULT_SOURCE

In glibc up to and including 2.19:

_BSD_SOURCE

DESCRIPTION

This interface is obsoleted by *rcmd*(3).

The **rexec**() function looks up the host **ahost* using *gethostbyname*(3), returning −1 if the host does not exist. Otherwise, **ahost* is set to the standard name of the host. If a username and password are both specified, then these are used to authenticate to the foreign host; otherwise the environment and then the *.netrc* file in user's home directory are searched for appropriate information. If all this fails, the user is prompted for the information.

The port *inport* specifies which well-known DARPA Internet port to use for the connection; the call *getservbyname("exec", "tcp")* (see *getservent*(3)) will return a pointer to a structure that contains the necessary port. The protocol for connection is described in detail in *rexecd*(8)

If the connection succeeds, a socket in the Internet domain of type **SOCK_STREAM** is returned to the caller, and given to the remote command as *stdin* and *stdout*. If *fd2p* is nonzero, then an auxiliary channel to a control process will be setup, and a file descriptor for it will be placed in **fd2p*. The control process will return diagnostic output from the command (unit 2) on this channel, and will also accept bytes on this channel as being UNIX signal numbers, to be forwarded to the process group of the command. The diagnostic information returned does not include remote authorization failure, as the secondary connection is set up after authorization has been verified. If *fd2p* is 0, then the *stderr* (unit 2 of the remote command) will be made the same as the *stdout* and no provision is made for sending arbitrary signals to the remote process, although you may be able to get its attention by using out-of-band data.

rexec_af()

The **rexec**() function works over IPv4 (**AF_INET**). By contrast, the **rexec_af**() function provides an extra argument, *af*, that allows the caller to select the protocol. This argument can be specified as **AF_INET**, **AF_INET6**, or **AF_UNSPEC** (to allow the implementation to select the protocol).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
rexec(), **rexec_af**()	Thread safety	MT-Unsafe

STANDARDS

None.

HISTORY

rexec() 4.2BSD, BSD, Solaris.

rexec_af()
glibc 2.2.

BUGS

The **rexec**() function sends the unencrypted password across the network.

The underlying service is considered a big security hole and therefore not enabled on many sites; see *rexecd*(8) for explanations.

SYNOPSIS

```
#include <math.h>

double nearbyint(double x);
float nearbyintf(float x);
long double nearbyintl(long double x);

double rint(double x);
float rintf(float x);
long double rintl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

nearbyint(), **nearbyintf**(), **nearbyintl**():
_POSIX_C_SOURCE >= 200112L || _ISOC99_SOURCE

rint():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| _XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

rintf(), **rintl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **nearbyint**(), **nearbyintf**(), and **nearbyintl**() functions round their argument to an integer value in floating-point format, using the current rounding direction (see *fesetround*(3)) and without raising the *inexact* exception. When the current rounding direction is to nearest, these functions round halfway cases to the even integer in accordance with IEEE-754.

The **rint**(), **rintf**(), and **rintl**() functions do the same, but will raise the *inexact* exception (**FE_INEXACT**, checkable via *fetestexcept*(3)) when the result differs in value from the argument.

RETURN VALUE

These functions return the rounded integer value.

If *x* is integral, +0, −0, NaN, or infinite, *x* itself is returned.

ERRORS

No errors occur. POSIX.1-2001 documents a range error for overflows, but see NOTES.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
nearbyint(), **nearbyintf**(), **nearbyintl**(), **rint**(), **rintf**(), **rintl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

NOTES

SUSv2 and POSIX.1-2001 contain text about overflow (which might set *errno* to **ERANGE**, or raise an **FE_OVERFLOW** exception). In practice, the result cannot overflow on any current machine, so this error-handling stuff is just nonsense. (More precisely, overflow can happen only when the maximum value of the exponent is smaller than the number of mantissa bits. For the IEEE-754 standard 32-bit and 64-bit floating-point numbers the maximum value of the exponent is 127 (respectively, 1023), and the number of mantissa bits including the implicit bit is 24 (respectively, 53).)

If you want to store the rounded value in an integer type, you probably want to use one of the functions described in *lrint*(3) instead.

SEE ALSO

ceil(3), *floor*(3), *lrint*(3), *round*(3), *trunc*(3)

NAME

round, roundf, roundl − round to nearest integer, away from zero

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double round(double x);
float roundf(float x);
long double roundl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

round(), **roundf**(), **roundl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions round *x* to the nearest integer, but round halfway cases away from zero (regardless of the current rounding direction, see *fenv*(3)), instead of to the nearest even integer like *rint*(3).

For example, *round(0.5)* is 1.0, and *round(−0.5)* is −1.0.

RETURN VALUE

These functions return the rounded integer value.

If *x* is integral, +0, −0, NaN, or infinite, *x* itself is returned.

ERRORS

No errors occur. POSIX.1-2001 documents a range error for overflows, but see NOTES.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
round(), **roundf**(), **roundl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

NOTES

POSIX.1-2001 contains text about overflow (which might set *errno* to **ERANGE**, or raise an **FE_OVERFLOW** exception). In practice, the result cannot overflow on any current machine, so this error-handling stuff is just nonsense. (More precisely, overflow can happen only when the maximum value of the exponent is smaller than the number of mantissa bits. For the IEEE-754 standard 32-bit and 64-bit floating-point numbers the maximum value of the exponent is 127 (respectively, 1023), and the number of mantissa bits including the implicit bit is 24 (respectively, 53).)

If you want to store the rounded value in an integer type, you probably want to use one of the functions described in *lround*(3) instead.

NAME

roundup − round up in steps

LIBRARY

Standard C library (*libc*)

SYNOPSIS

#include <sys/param.h>

roundup(*x***,** *step***);**

DESCRIPTION

This macro rounds *x* to the nearest multiple of *step* that is not less than *x*.

It is typically used for rounding up a pointer to align it or increasing a buffer to be allocated.

This API is not designed to be generic, and doesn't work in some cases that are not important for the typical use cases described above. See CAVEATS.

RETURN VALUE

This macro returns the rounded value.

STANDARDS

None.

CAVEATS

The arguments may be evaluated more than once.

x should be nonnegative, and *step* should be positive.

If *x* + *step* would overflow or wrap around, the behavior is undefined.

SEE ALSO

ceil(3), *floor*(3), *lrint*(3), *rint*(3), *lround*(3), *round*(3)

NAME

rpc − library routines for remote procedure calls

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS AND DESCRIPTION

These routines allow C programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a data packet to the server. Upon receipt of the packet, the server calls a dispatch routine to perform the requested service, and then sends back a reply. Finally, the procedure call returns to the client.

To take use of these routines, include the header file *<rpc/rpc.h>*.

The prototypes below make use of the following types:

```
typedef int bool_t;

typedef bool_t (*xdrproc_t)(XDR *, void *, ...);

typedef bool_t (*resultproc_t)(caddr_t resp,
                               struct sockaddr_in *raddr);
```

See the header files for the declarations of the *AUTH*, *CLIENT*, *SVCXPRT*, and *XDR* types.

void auth_destroy(AUTH *****auth***);**

A macro that destroys the authentication information associated with *auth*. Destruction usually involves deallocation of private data structures. The use of *auth* is undefined after calling **auth_destroy**().

AUTH *authnone_create(void);

Create and return an RPC authentication handle that passes nonusable authentication information with each remote procedure call. This is the default authentication used by RPC.

AUTH *authunix_create(char ***host*, uid_t** *uid***, gid_t** *gid***,**
int *len***, gid_t** *aup_gids***[.**len**]);**

Create and return an RPC authentication handle that contains authentication information. The parameter *host* is the name of the machine on which the information was created; *uid* is the user's user ID; *gid* is the user's current group ID; *len* and *aup_gids* refer to a counted array of groups to which the user belongs. It is easy to impersonate a user.

AUTH *authunix_create_default(void);

Calls **authunix_create**() with the appropriate parameters.

int callrpc(char ***host*, unsigned long** *prognum***,**
unsigned long *versnum***, unsigned long** *procnum***,**
xdrproc_t *inproc***, const char ***in***,**
xdrproc_t *outproc***, char ***out***);**

Call the remote procedure associated with *prognum*, *versnum*, and *procnum* on the machine, *host*. The parameter *in* is the address of the procedure's argument(s), and *out* is the address of where to place the result(s); *inproc* is used to encode the procedure's parameters, and *outproc* is used to decode the procedure's results. This routine returns zero if it succeeds, or the value of **enum clnt_stat** cast to an integer if it fails. The routine **clnt_perrno**() is handy for translating failure statuses into messages.

Warning: calling remote procedures with this routine uses UDP/IP as a transport; see **clntudp_create**() for restrictions. You do not have control of timeouts or authentication using this routine.

enum clnt_stat clnt_broadcast(unsigned long *prognum***,**
unsigned long *versnum***, unsigned long** *procnum***,**
xdrproc_t *inproc***, char ***in***,**
xdrproc_t *outproc***, char ***out***,**
resultproc_t *eachresult***);**

Like **callrpc**(), except the call message is broadcast to all locally connected broadcast nets. Each time it receives a response, this routine calls **eachresult**(), whose form is:

```
eachresult(char *out, struct sockaddr_in *addr);
```

where *out* is the same as *out* passed to **clnt_broadcast**(), except that the remote procedure's output is decoded there; *addr* points to the address of the machine that sent the results. If **eachresult**() returns zero, **clnt_broadcast**() waits for more replies; otherwise it returns with appropriate status.

Warning: broadcast sockets are limited in size to the maximum transfer unit of the data link. For ethernet, this value is 1500 bytes.

enum clnt_stat clnt_call(CLIENT ****clnt*, unsigned long** *procnum***,**
xdrproc_t *inproc***, char ****in***,**
xdrproc_t *outproc***, char ****out***,**
struct timeval *tout***);**

A macro that calls the remote procedure *procnum* associated with the client handle, *clnt*, which is obtained with an RPC client creation routine such as **clnt_create**(). The parameter *in* is the address of the procedure's argument(s), and *out* is the address of where to place the result(s); *inproc* is used to encode the procedure's parameters, and *outproc* is used to decode the procedure's results; *tout* is the time allowed for results to come back.

clnt_destroy(CLIENT ****clnt*);**

A macro that destroys the client's RPC handle. Destruction usually involves deallocation of private data structures, including *clnt* itself. Use of *clnt* is undefined after calling **clnt_destroy**(). If the RPC library opened the associated socket, it will close it also. Otherwise, the socket remains open.

CLIENT *clnt_create(const char ****host*, unsigned long** *prog***,**
unsigned long *vers***, const char ****proto***);**

Generic client creation routine. *host* identifies the name of the remote host where the server is located. *proto* indicates which kind of transport protocol to use. The currently supported values for this field are "udp" and "tcp". Default timeouts are set, but can be modified using **clnt_control**().

Warning: using UDP has its shortcomings. Since UDP-based RPC messages can hold only up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

bool_t clnt_control(CLIENT ****cl*, int** *req***, char ****info***);**

A macro used to change or retrieve various information about a client object. *req* indicates the type of operation, and *info* is a pointer to the information. For both UDP and TCP, the supported values of *req* and their argument types and what they do are:

```
CLSET_TIMEOUT  struct timeval // set total timeout
CLGET_TIMEOUT  struct timeval // get total timeout
```

Note: if you set the timeout using **clnt_control**(), the timeout parameter passed to **clnt_call**() will be ignored in all future calls.

```
CLGET_SERVER_ADDR  struct sockaddr_in
                  // get server's address
```

The following operations are valid for UDP only:

```
CLSET_RETRY_TIMEOUT  struct timeval // set the retry timeout
CLGET_RETRY_TIMEOUT  struct timeval // get the retry timeout
```

The retry timeout is the time that "UDP RPC" waits for the server to reply before retransmitting the request.

clnt_freeres(CLIENT * *clnt***, xdrproc_t** *outproc***, char ****out***);**

A macro that frees any data allocated by the RPC/XDR system when it decoded the results of an RPC call. The parameter *out* is the address of the results, and *outproc* is the XDR routine describing the results. This routine returns one if the results were successfully freed, and zero

otherwise.

void clnt_geterr(CLIENT ****clnt*, struct rpc_err ****errp***);**

A macro that copies the error structure out of the client handle to the structure at address *errp*.

void clnt_pcreateerror(const char ****s*);**

Print a message to standard error indicating why a client RPC handle could not be created. The message is prepended with string *s* and a colon. Used when a **clnt_create**(), **clntraw_create**(), **clnttcp_create**(), or **clntudp_create**() call fails.

void clnt_perrno(enum clnt_stat *stat***);**

Print a message to standard error corresponding to the condition indicated by *stat*. Used after **callrpc**().

clnt_perror(CLIENT ****clnt*, const char ****s***);**

Print a message to standard error indicating why an RPC call failed; *clnt* is the handle used to do the call. The message is prepended with string *s* and a colon. Used after **clnt_call**().

char *clnt_spcreateerror(const char ****s*);**

Like **clnt_pcreateerror**(), except that it returns a string instead of printing to the standard error.

Bugs: returns pointer to static data that is overwritten on each call.

char *clnt_sperrno(enum clnt_stat *stat***);**

Take the same arguments as **clnt_perrno**(), but instead of sending a message to the standard error indicating why an RPC call failed, return a pointer to a string which contains the message. The string ends with a NEWLINE.

clnt_sperrno() is used instead of **clnt_perrno**() if the program does not have a standard error (as a program running as a server quite likely does not), or if the programmer does not want the message to be output with *printf*(3), or if a message format different than that supported by **clnt_perrno**() is to be used. Note: unlike **clnt_sperror**() and **clnt_spcreateerror**(), **clnt_sperrno**() returns pointer to static data, but the result will not get overwritten on each call.

char *clnt_sperror(CLIENT ****rpch*, const char ****s***);**

Like **clnt_perror**(), except that (like *clnt_sperrno*()) it returns a string instead of printing to standard error.

Bugs: returns pointer to static data that is overwritten on each call.

CLIENT *clntraw_create(unsigned long *prognum***, unsigned long** *versnum***);**

This routine creates a toy RPC client for the remote program *prognum*, version *versnum*. The transport used to pass messages to the service is actually a buffer within the process's address space, so the corresponding RPC server should live in the same address space; see **svcraw_create**(). This allows simulation of RPC and acquisition of RPC overheads, such as round trip times, without any kernel interference. This routine returns NULL if it fails.

CLIENT *clnttcp_create(struct sockaddr_in ****addr*,**
unsigned long *prognum***, unsigned long** *versnum***,**
int ****sockp*, unsigned int** *sendsz***, unsigned int** *recvsz***);**

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses TCP/IP as a transport. The remote program is located at Internet address **addr*. If *addr*−>*sin_port* is zero, then it is set to the actual port that the remote program is listening on (the remote **portmap** service is consulted for this information). The parameter *sockp* is a socket; if it is **RPC_ANYSOCK**, then this routine opens a new one and sets *sockp*. Since TCP-based RPC uses buffered I/O, the user may specify the size of the send and receive buffers with the parameters *sendsz* and *recvsz*; values of zero choose suitable defaults. This routine returns NULL if it fails.

CLIENT *clntudp_create(struct sockaddr_in ****addr*,**
unsigned long *prognum***, unsigned long** *versnum***,**

struct timeval *wait***, int ***sockp**);**

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses use UDP/IP as a transport. The remote program is located at Internet address *addr*. If *addr−>sin_port* is zero, then it is set to actual port that the remote program is listening on (the remote **portmap** service is consulted for this information). The parameter *sockp* is a socket; if it is **RPC_ANYSOCK**, then this routine opens a new one and sets *sockp*. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by **clnt_call**().

Warning: since UDP-based RPC messages can hold only up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

CLIENT *clntudp_bufcreate(struct sockaddr_in ***_addr_,**
unsigned long *prognum***, unsigned long** *versnum***,**
struct timeval *wait***, int ***_sockp_**,**
unsigned int *sendsize***, unsigned int** *recosize***);**

This routine creates an RPC client for the remote program *prognum*, on *versnum*; the client uses use UDP/IP as a transport. The remote program is located at Internet address *addr*. If *addr−>sin_port* is zero, then it is set to actual port that the remote program is listening on (the remote **portmap** service is consulted for this information). The parameter *sockp* is a socket; if it is **RPC_ANYSOCK**, then this routine opens a new one and sets *sockp*. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by **clnt_call**().

This allows the user to specify the maximum packet size for sending and receiving UDP-based RPC messages.

void get_myaddress(struct sockaddr_in ***_addr_);**

Stuff the machine's IP address into **addr*, without consulting the library routines that deal with */etc/hosts*. The port number is always set to **htons(PMAPPORT)**.

struct pmaplist *pmap_getmaps(struct sockaddr_in ***_addr_);**

A user interface to the **portmap** service, which returns a list of the current RPC program-to-port mappings on the host located at IP address **addr*. This routine can return NULL. The command *rpcinfo −p* uses this routine.

unsigned short pmap_getport(struct sockaddr_in ***_addr_,**
unsigned long *prognum***, unsigned long** *versnum***,**
unsigned int *protocol***);**

A user interface to the **portmap** service, which returns the port number on which waits a service that supports program number *prognum*, version *versnum*, and speaks the transport protocol associated with *protocol*. The value of *protocol* is most likely **IPPROTO_UDP** or **IPPROTO_TCP**. A return value of zero means that the mapping does not exist or that the RPC system failed to contact the remote **portmap** service. In the latter case, the global variable *rpc_createerr* contains the RPC status.

enum clnt_stat pmap_rmtcall(struct sockaddr_in ***_addr_,**
unsigned long *prognum***, unsigned long** *versnum***,**
unsigned long *procnum***,**
xdrproc_t *inproc***, char ***_in_**,**
xdrproc_t *outproc***, char ***_out_**,**
struct timeval *tout***, unsigned long ***_portp_**);**

A user interface to the **portmap** service, which instructs **portmap** on the host at IP address **addr* to make an RPC call on your behalf to a procedure on that host. The parameter **portp* will be modified to the program's port number if the procedure succeeds. The definitions of other parameters are discussed in **callrpc**() and **clnt_call**(). This procedure should be used for a "ping" and nothing else. See also **clnt_broadcast**().

bool_t pmap_set(unsigned long *prognum***, unsigned long** *versnum***,**
int *protocol***, unsigned short** *port***);**

A user interface to the **portmap** service, which establishes a mapping between the triple [*prognum*,*versnum*,*protocol*] and *port* on the machine's **portmap** service. The value of *protocol* is most likely **IPPROTO_UDP** or **IPPROTO_TCP**. This routine returns one if it succeeds, zero otherwise. Automatically done by **svc_register**().

bool_t pmap_unset(unsigned long *prognum***, unsigned long** *versnum***);**

A user interface to the **portmap** service, which destroys all mapping between the triple [*prognum*,*versnum*,*] and **ports** on the machine's **portmap** service. This routine returns one if it succeeds, zero otherwise.

int registerrpc(unsigned long *prognum***, unsigned long** *versnum***,**
unsigned long *procnum***, char *(*******procname***)(char *),**
xdrproc_t *inproc***, xdrproc_t** *outproc***);**

Register procedure *procname* with the RPC service package. If a request arrives for program *prognum*, version *versnum*, and procedure *procnum*, *procname* is called with a pointer to its parameter(s); *procname* should return a pointer to its static result(s); *inproc* is used to decode the parameters while *outproc* is used to encode the results. This routine returns zero if the registration succeeded, −1 otherwise.

Warning: remote procedures registered in this form are accessed using the UDP/IP transport; see **svcudp_create**() for restrictions.

struct rpc_createerr *rpc_createerr***;**

A global variable whose value is set by any RPC client creation routine that does not succeed. Use the routine **clnt_pcreateerror**() to print the reason why.

void svc_destroy(SVCXPRT * *xprt***);**

A macro that destroys the RPC service transport handle, *xprt*. Destruction usually involves deallocation of private data structures, including *xprt* itself. Use of *xprt* is undefined after calling this routine.

fd_set *svc_fdset***;**

A global variable reflecting the RPC service side's read file descriptor bit mask; it is suitable as a parameter to the *select*(2) system call. This is of interest only if a service implementor does their own asynchronous event processing, instead of calling **svc_run**(). This variable is read-only (do not pass its address to *select*(2)!), yet it may change after calls to **svc_getreqset**() or any creation routines.

int *svc_fds***;**

Similar to **svc_fdset**, but limited to 32 file descriptors. This interface is obsoleted by **svc_fdset**.

svc_freeargs(SVCXPRT * *xprt***, xdrproc_t** *inproc***, char *** *in***);**

A macro that frees any data allocated by the RPC/XDR system when it decoded the arguments to a service procedure using **svc_getargs**(). This routine returns 1 if the results were successfully freed, and zero otherwise.

svc_getargs(SVCXPRT * *xprt***, xdrproc_t** *inproc***, char *** *in***);**

A macro that decodes the arguments of an RPC request associated with the RPC service transport handle, *xprt*. The parameter *in* is the address where the arguments will be placed; *inproc* is the XDR routine used to decode the arguments. This routine returns one if decoding succeeds, and zero otherwise.

struct sockaddr_in *svc_getcaller(SVCXPRT * *xprt***);**

The approved way of getting the network address of the caller of a procedure associated with the RPC service transport handle, *xprt*.

void svc_getreqset(fd_set * *rdfds***);**

This routine is of interest only if a service implementor does not call **svc_run**(), but instead implements custom asynchronous event processing. It is called when the *select*(2) system call has determined that an RPC request has arrived on some RPC socket(s); *rdfds* is the resultant

read file descriptor bit mask. The routine returns when all sockets associated with the value of *rdfds* have been serviced.

void svc_getreq(int *rdfds***);**

Similar to **svc_getreqset**(), but limited to 32 file descriptors. This interface is obsoleted by **svc_getreqset**().

bool_t svc_register(SVCXPRT * *xprt***, unsigned long** *prognum***,**
unsigned long *versnum***,**
void (* *dispatch***)(struct svc_req *, SVCXPRT *),**
unsigned long *protocol***);**

Associates *prognum* and *versnum* with the service dispatch procedure, *dispatch*. If *protocol* is zero, the service is not registered with the **portmap** service. If *protocol* is nonzero, then a mapping of the triple [*prognum*,*versnum*,*protocol*] to *xprt*−>*xp_port* is established with the local **portmap** service (generally *protocol* is zero, **IPPROTO_UDP** or **IPPROTO_TCP**). The procedure *dispatch* has the following form:

```
dispatch(struct svc_req *request, SVCXPRT *xprt);
```

The **svc_register**() routine returns one if it succeeds, and zero otherwise.

void svc_run(void);

This routine never returns. It waits for RPC requests to arrive, and calls the appropriate service procedure using **svc_getreq**() when one arrives. This procedure is usually waiting for a *select*(2) system call to return.

bool_t svc_sendreply(SVCXPRT * *xprt***, xdrproc_t** *outproc***, char *** *out***);**

Called by an RPC service's dispatch routine to send the results of a remote procedure call. The parameter *xprt* is the request's associated transport handle; *outproc* is the XDR routine which is used to encode the results; and *out* is the address of the results. This routine returns one if it succeeds, zero otherwise.

void svc_unregister(unsigned long *prognum***, unsigned long** *versnum***);**

Remove all mapping of the double [*prognum*,*versnum*] to dispatch routines, and of the triple [*prognum*,*versnum*,*] to port number.

void svcerr_auth(SVCXPRT * *xprt***, enum auth_stat** *why***);**

Called by a service dispatch routine that refuses to perform a remote procedure call due to an authentication error.

void svcerr_decode(SVCXPRT * *xprt***);**

Called by a service dispatch routine that cannot successfully decode its parameters. See also **svc_getargs**().

void svcerr_noproc(SVCXPRT * *xprt***);**

Called by a service dispatch routine that does not implement the procedure number that the caller requests.

void svcerr_noprog(SVCXPRT * *xprt***);**

Called when the desired program is not registered with the RPC package. Service implementors usually do not need this routine.

void svcerr_progvers(SVCXPRT * *xprt***, unsigned long** *low_vers***,**
unsigned long *high_vers***);**

Called when the desired version of a program is not registered with the RPC package. Service implementors usually do not need this routine.

void svcerr_systemerr(SVCXPRT * *xprt***);**

Called by a service dispatch routine when it detects a system error not covered by any particular protocol. For example, if a service can no longer allocate storage, it may call this routine.

void svcerr_weakauth(SVCXPRT * *xprt***);**

Called by a service dispatch routine that refuses to perform a remote procedure call due to insufficient authentication parameters. The routine calls **svcerr_auth(xprt, AUTH_TOOWEAK)**.

SVCXPRT *svcfd_create(int *fd***, unsigned int** *sendsize***,**
unsigned int *recvsize***);**

Create a service on top of any open file descriptor. Typically, this file descriptor is a connected socket for a stream protocol such as TCP. *sendsize* and *recvsize* indicate sizes for the send and receive buffers. If they are zero, a reasonable default is chosen.

SVCXPRT *svcraw_create(void);

This routine creates a toy RPC service transport, to which it returns a pointer. The transport is really a buffer within the process's address space, so the corresponding RPC client should live in the same address space; see **clntraw_create**(). This routine allows simulation of RPC and acquisition of RPC overheads (such as round trip times), without any kernel interference. This routine returns NULL if it fails.

SVCXPRT *svctcp_create(int *sock***, unsigned int** *send_buf_size***,**
unsigned int *recv_buf_size***);**

This routine creates a TCP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *sock*, which may be **RPC_ANYSOCK**, in which case a new socket is created. If the socket is not bound to a local TCP port, then this routine binds it to an arbitrary port. Upon completion, *xprt−>xp_sock* is the transport's socket descriptor, and *xprt−>xp_port* is the transport's port number. This routine returns NULL if it fails. Since TCP-based RPC uses buffered I/O, users may specify the size of buffers; values of zero choose suitable defaults.

SVCXPRT *svcudp_bufcreate(int *sock***, unsigned int** *sendsize***,**
unsigned int *recosize***);**

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *sock*, which may be **RPC_ANYSOCK**, in which case a new socket is created. If the socket is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, *xprt−>xp_sock* is the transport's socket descriptor, and *xprt−>xp_port* is the transport's port number. This routine returns NULL if it fails.

This allows the user to specify the maximum packet size for sending and receiving UDP-based RPC messages.

SVCXPRT *svcudp_create(int *sock***);**

This call is equivalent to *svcudp_bufcreate(sock,SZ,SZ)* for some default size *SZ*.

bool_t xdr_accepted_reply(XDR * *xdrs***, struct accepted_reply *** *ar***);**

Used for encoding RPC reply messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t xdr_authunix_parms(XDR * *xdrs***, struct authunix_parms *** *aupp***);**

Used for describing UNIX credentials. This routine is useful for users who wish to generate these credentials without using the RPC authentication package.

void xdr_callhdr(XDR * *xdrs***, struct rpc_msg *** *chdr***);**

Used for describing RPC call header messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t xdr_callmsg(XDR * *xdrs***, struct rpc_msg *** *cmsg***);**

Used for describing RPC call messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t xdr_opaque_auth(XDR * *xdrs***, struct opaque_auth *** *ap***);**

Used for describing RPC authentication information messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t xdr_pmap(XDR * *xdrs***, struct pmap *** *regs***);**

Used for describing parameters to various **portmap** procedures, externally. This routine is useful for users who wish to generate these parameters without using the **pmap** interface.

bool_t xdr_pmaplist(XDR ****xdrs*, struct pmaplist *****rp***);**

Used for describing a list of port mappings, externally. This routine is useful for users who wish to generate these parameters without using the **pmap** interface.

bool_t xdr_rejected_reply(XDR ****xdrs*, struct rejected_reply ****rr***);**

Used for describing RPC reply messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t xdr_replymsg(XDR ****xdrs*, struct rpc_msg ****rmsg***);**

Used for describing RPC reply messages. This routine is useful for users who wish to generate RPC style messages without using the RPC package.

void xprt_register(SVCXPRT ****xprt*);**

After RPC service transport handles are created, they should register themselves with the RPC service package. This routine modifies the global variable *svc_fds*. Service implementors usually do not need this routine.

void xprt_unregister(SVCXPRT ****xprt*);**

Before an RPC service transport handle is destroyed, it should unregister itself with the RPC service package. This routine modifies the global variable *svc_fds*. Service implementors usually do not need this routine.

NAME

rpmatch − determine if the answer to a question is affirmative or negative

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int rpmatch(const char ****response*);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

rpmatch():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_SVID_SOURCE

DESCRIPTION

rpmatch() handles a user response to yes or no questions, with support for internationalization.

response should be a null-terminated string containing a user-supplied response, perhaps obtained with *fgets*(3) or *getline*(3).

The user's language preference is taken into account per the environment variables **LANG**, **LC_MESSAGES**, and **LC_ALL**, if the program has called *setlocale*(3) to effect their changes.

Regardless of the locale, responses matching **^[Yy]** are always accepted as affirmative, and those matching **^[Nn]** are always accepted as negative.

RETURN VALUE

After examining *response*, **rpmatch**() returns 0 for a recognized negative response ("no"), 1 for a recognized positive response ("yes"), and −1 when the value of *response* is unrecognized.

ERRORS

A return value of −1 may indicate either an invalid input, or some other error. It is incorrect to only test if the return value is nonzero.

rpmatch() can fail for any of the reasons that *regcomp*(3) or *regexec*(3) can fail; the cause of the error is not available from *errno* or anywhere else, but indicates a failure of the regex engine (but this case is indistinguishable from that of an unrecognized value of *response*).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
rpmatch()	Thread safety	MT-Safe locale

STANDARDS

None.

HISTORY

GNU, FreeBSD, AIX.

BUGS

The **YESEXPR** and **NOEXPR** of some locales (including "C") only inspect the first character of the *response*. This can mean that "yno" et al. resolve to **1**. This is an unfortunate historical side-effect which should be fixed in time with proper localisation, and should not deter from **rpmatch**() being the proper way to distinguish between binary answers.

EXAMPLES

The following program displays the results when **rpmatch**() is applied to the string given in the program's command-line argument.

```
#define _DEFAULT_SOURCE
#include <locale.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
```

```
int
main(int argc, char *argv[])
{
    if (argc != 2 || strcmp(argv[1], "--help") == 0) {
        fprintf(stderr, "%s response\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    setlocale(LC_ALL, "");
    printf("rpmatch() returns: %d\n", rpmatch(argv[1]));
    exit(EXIT_SUCCESS);
}
```

NAME

rtime − get time from a remote machine

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <rpc/auth_des.h>

int rtime(struct sockaddr_in ****addrp*, struct rpc_timeval ****timep***,**
struct rpc_timeval ****timeout*);**

DESCRIPTION

This function uses the Time Server Protocol as described in RFC 868 to obtain the time from a remote machine.

The Time Server Protocol gives the time in seconds since 00:00:00 UTC, 1 Jan 1900, and this function subtracts the appropriate constant in order to convert the result to seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC).

When *timeout* is non-NULL, the udp/time socket (port 37) is used. Otherwise, the tcp/time socket (port 37) is used.

RETURN VALUE

On success, 0 is returned, and the obtained 32-bit time value is stored in *timep−>tv_sec*. In case of error −1 is returned, and *errno* is set to indicate the error.

ERRORS

All errors for underlying functions (**sendto**(2), *poll*(2), *recvfrom*(2), *connect*(2), *read*(2)) can occur. Moreover:

EIO The number of returned bytes is not 4.

ETIMEDOUT
The waiting time as defined in timeout has expired.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
rtime()	Thread safety	MT-Safe

NOTES

Only IPv4 is supported.

Some *in.timed* versions support only TCP. Try the example program with *use_tcp* set to 1.

BUGS

rtime() in glibc 2.2.5 and earlier does not work properly on 64-bit machines.

EXAMPLES

This example requires that port 37 is up and open. You may check that the time entry within */etc/inetd.conf* is not commented out.

The program connects to a computer called "linux". Using "localhost" does not work. The result is the localtime of the computer "linux".

```
#include <errno.h>
#include <netdb.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <time.h>

#include <rpc/auth_des.h>

static int use_tcp = 0;
static const char servername[] = "linux";

int
```

```
main(void)
{
    int                 ret;
    time_t              t;
    struct hostent      *hent;
    struct rpc_timeval  time1 = {0, 0};
    struct rpc_timeval  timeout = {1, 0};
    struct sockaddr_in  name;

    memset(&name, 0, sizeof(name));
    sethostent(1);
    hent = gethostbyname(servername);
    memcpy(&name.sin_addr, hent->h_addr, hent->h_length);

    ret = rtime(&name, &time1, use_tcp ? NULL : &timeout);
    if (ret < 0)
        perror("rtime error");
    else {
        t = time1.tv_sec;
        printf("%s\n", ctime(&t));
    }

    exit(EXIT_SUCCESS);
}
```

NAME

rtnetlink − macros to manipulate rtnetlink messages

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <asm/types.h>
#include <linux/netlink.h>
#include <linux/rtnetlink.h>
#include <sys/socket.h>

rtnetlink_socket = socket(AF_NETLINK, int *socket_type***, NETLINK_ROUTE);**

int RTA_OK(struct rtattr ***_rta_, int** *rtabuflen***);**

void *RTA_DATA(struct rtattr ***_rta_);**
unsigned int RTA_PAYLOAD(struct rtattr ***_rta_);**

struct rtattr *RTA_NEXT(struct rtattr ***_rta_, unsigned int** *rtabuflen***);**

unsigned int RTA_LENGTH(unsigned int *length***);**
unsigned int RTA_SPACE(unsigned int *length***);**

DESCRIPTION

All *rtnetlink*(7) messages consist of a *netlink*(7) message header and appended attributes. The attributes should be manipulated only using the macros provided here.

RTA_OK(*rta***,** *attrlen***)** returns true if *rta* points to a valid routing attribute; *attrlen* is the running length of the attribute buffer. When not true then you must assume there are no more attributes in the message, even if *attrlen* is nonzero.

RTA_DATA(*rta***)** returns a pointer to the start of this attribute's data.

RTA_PAYLOAD(*rta***)** returns the length of this attribute's data.

RTA_NEXT(*rta***,** *attrlen***)** gets the next attribute after *rta*. Calling this macro will update *attrlen*. You should use **RTA_OK** to check the validity of the returned pointer.

RTA_LENGTH(*len***)** returns the length which is required for *len* bytes of data plus the header.

RTA_SPACE(*len***)** returns the amount of space which will be needed in a message with *len* bytes of data.

STANDARDS

Linux.

BUGS

This manual page is incomplete.

EXAMPLES

Creating a rtnetlink message to set the MTU of a device:

```
#include <linux/rtnetlink.h>

...

struct {
    struct nlmsghdr  nh;
    struct ifinfomsg if;
    char             attrbuf[512];
} req;

struct rtattr *rta;
unsigned int mtu = 1000;

int rtnetlink_sk = socket(AF_NETLINK, SOCK_DGRAM, NETLINK_ROUTE);

memset(&req, 0, sizeof(req));
```

```
        req.nh.nlmsg_len = NLMSG_LENGTH(sizeof(req.if));
        req.nh.nlmsg_flags = NLM_F_REQUEST;
        req.nh.nlmsg_type = RTM_NEWLINK;
        req.if.ifi_family = AF_UNSPEC;
        req.if.ifi_index = INTERFACE_INDEX;
        req.if.ifi_change = 0xffffffff; /* ??? */
        rta = (struct rtattr *)(((char *) &req) +
                                NLMSG_ALIGN(req.nh.nlmsg_len));
        rta->rta_type = IFLA_MTU;
        rta->rta_len = RTA_LENGTH(sizeof(mtu));
        req.nh.nlmsg_len = NLMSG_ALIGN(req.nh.nlmsg_len) +
                                       RTA_LENGTH(sizeof(mtu));
        memcpy(RTA_DATA(rta), &mtu, sizeof(mtu));
        send(rtnetlink_sk, &req, req.nh.nlmsg_len, 0);
```

NAME

scalb, scalbf, scalbl − multiply floating-point number by integral power of radix (OBSOLETE)

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

[[deprecated]] double scalb(double x, double exp);
[[deprecated]] float scalbf(float x, float exp);
[[deprecated]] long double scalbl(long double x, long double exp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

scalb():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

scalbf(), **scalbl**():
_XOPEN_SOURCE >= 600
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions multiply their first argument *x* by **FLT_RADIX** (probably 2) to the power of *exp*, that is:

```
x * FLT_RADIX ** exp
```

The definition of **FLT_RADIX** can be obtained by including <*float.h*>.

RETURN VALUE

On success, these functions return *x* * **FLT_RADIX** ** *exp*.

If *x* or *exp* is a NaN, a NaN is returned.

If *x* is positive infinity (negative infinity), and *exp* is not negative infinity, positive infinity (negative infinity) is returned.

If *x* is +0 (−0), and *exp* is not positive infinity, +0 (−0) is returned.

If *x* is zero, and *exp* is positive infinity, a domain error occurs, and a NaN is returned.

If *x* is an infinity, and *exp* is negative infinity, a domain error occurs, and a NaN is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with a sign the same as *x*.

If the result underflows, a range error occurs, and the functions return zero, with a sign the same as *x*.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is 0, and *exp* is positive infinity, or *x* is positive infinity and *exp* is negative infinity and the other argument is not a NaN
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

Range error, overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error, underflow
: *errno* is set to **ERANGE**. An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
scalb(), **scalbf**(), **scalbl**()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

scalb() 4.3BSD. Obsolescent in POSIX.1-2001; Removed in POSIX.1-2008, recommending the use of *scalbln*(3), *scalblnf*(3), or *scalblnl*(3) instead.

BUGS

Before glibc 2.20, these functions did not set *errno* for domain and range errors.

SEE ALSO

ldexp(3), *scalbln*(3)

NAME

|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions multiply their first argument *x* by **FLT_RADIX** (probably 2) to the power of *exp*, that is:

```
x * FLT_RADIX ** exp
```

The definition of **FLT_RADIX** can be obtained by including <*float.h*>.

RETURN VALUE

On success, these functions return *x* * **FLT_RADIX** ** *exp*.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity (negative infinity), positive infinity (negative infinity) is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with a sign the same as *x*.

If the result underflows, a range error occurs, and the functions return zero, with a sign the same as *x*.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error, overflow
: An overflow floating-point exception (**FE_OVERFLOW**) is raised.

Range error, underflow
: *errno* is set to **ERANGE**. An underflow floating-point exception (**FE_UNDERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
scalbn(), **scalbnf**(), **scalbnl**(), **scalbln**(), **scalblnf**(), **scalblnl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

HISTORY

These functions differ from the obsolete functions described in *scalb*(3) in the type of their second argument. The functions described on this page have a second argument of an integral type, while those in *scalb*(3) have a second argument of type *double*.

NOTES

If **FLT_RADIX** equals 2 (which is usual), then **scalbn**() is equivalent to *ldexp*(3).

BUGS

Before glibc 2.20, these functions did not set *errno* for range errors.

SEE ALSO

ldexp(3), *scalb*(3)

NAME

scandir, scandirat, alphasort, versionsort − scan a directory for matching entries

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <dirent.h>

int scandir(const char *restrict dirp,
        struct dirent ***restrict namelist,
        int (* filter)(const struct dirent *),
        int (*compar)(const struct dirent **,
                const struct dirent **));

int alphasort(const struct dirent **a, const struct dirent **b);
int versionsort(const struct dirent **a, const struct dirent **b);

#include <fcntl.h>          /* Definition of AT_* constants */
#include <dirent.h>

int scandirat(int dirfd, const char *restrict dirp,
        struct dirent ***restrict namelist,
        int (* filter)(const struct dirent *),
        int (*compar)(const struct dirent **,
                const struct dirent **));
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

scandir(), **alphasort**():

```
/* Since glibc 2.10: */ _POSIX_C_SOURCE >= 200809L
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

versionsort():

```
_GNU_SOURCE
```

scandirat():

```
_GNU_SOURCE
```

DESCRIPTION

The **scandir**() function scans the directory *dirp*, calling *filter*() on each directory entry. Entries for which *filter*() returns nonzero are stored in strings allocated via *malloc*(3), sorted using *qsort*(3) with the comparison function *compar*(), and collected in array *namelist* which is allocated via *malloc*(3). If *filter* is NULL, all entries are selected.

The **alphasort**() and **versionsort**() functions can be used as the comparison function *compar*(). The former sorts directory entries using *strcoll*(3), the latter using *strverscmp*(3) on the strings *(*a)−>d_name* and *(*b)−>d_name*.

scandirat()

The **scandirat**() function operates in exactly the same way as **scandir**(), except for the differences described here.

If the pathname given in *dirp* is relative, then it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by **scandir**() for a relative pathname).

If *dirp* is relative and *dirfd* is the special value **AT_FDCWD**, then *dirp* is interpreted relative to the current working directory of the calling process (like *scandir*())

If *dirp* is absolute, then *dirfd* is ignored.

See *openat*(2) for an explanation of the need for **scandirat**().

RETURN VALUE

The **scandir**() function returns the number of directory entries selected. On error, −1 is returned, with *errno* set to indicate the error.

The **alphasort**() and **versionsort**() functions return an integer less than, equal to, or greater than zero if the first argument is considered to be respectively less than, equal to, or greater than the second.

ERRORS

EBADF
(**scandirat**()) *dirp* is relative but *dirfd* is neither **AT_FDCWD** nor a valid file descriptor.

ENOENT
The path in *dirp* does not exist.

ENOMEM
Insufficient memory to complete the operation.

ENOTDIR
The path in *dirp* is not a directory.

ENOTDIR
(**scandirat**()) *dirp* is a relative pathname and *dirfd* is a file descriptor referring to a file other than a directory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
scandir(), **scandirat**()	Thread safety	MT-Safe
alphasort(), **versionsort**()	Thread safety	MT-Safe locale

STANDARDS

alphasort()
scandir()
POSIX.1-2008.

versionsort()
scandirat()
GNU.

HISTORY

alphasort()
scandir()
4.3BSD, POSIX.1-2008.

versionsort()
glibc 2.1.

scandirat()
glibc 2.15.

NOTES

Since glibc 2.1, **alphasort**() calls *strcoll*(3); earlier it used *strcmp*(3).

Before glibc 2.10, the two arguments of **alphasort**() and **versionsort**() were typed as *const void* *. When **alphasort**() was standardized in POSIX.1-2008, the argument type was specified as the type-safe *const struct dirent* **, and glibc 2.10 changed the definition of **alphasort**() (and the nonstandard *versionsort*()) to match the standard.

EXAMPLES

The program below prints a list of the files in the current directory in reverse order.

Program source

```
#define _DEFAULT_SOURCE
#include <dirent.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    struct dirent **namelist;
    int n;
```

```
        n = scandir(".", &namelist, NULL, alphasort);
        if (n == -1) {
            perror("scandir");
            exit(EXIT_FAILURE);
        }

        while (n--) {
            printf("%s\n", namelist[n]->d_name);
            free(namelist[n]);
        }
        free(namelist);

        exit(EXIT_SUCCESS);
    }
```

SEE ALSO

NAME

scanf, fscanf, vscanf, vfscanf − input FILE format conversion

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int scanf(const char *restrict format, ...);
int fscanf(FILE *restrict stream,
        const char *restrict format, ...);

#include <stdarg.h>

int vscanf(const char *restrict format, va_list ap);
int vfscanf(FILE *restrict stream,
        const char *restrict format, va_list ap);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

vscanf(), **vfscanf**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **scanf**() family of functions scans formatted input like *sscanf*(3), but read from a *FILE*. It is very difficult to use these functions correctly, and it is preferable to read entire lines with *fgets*(3) or *getline*(3) and parse them later with *sscanf*(3) or more specialized functions such as *strtol*(3).

The **scanf**() function reads input from the standard input stream *stdin* and **fscanf**() reads input from the stream pointer *stream*.

The **vfscanf**() function is analogous to *vfprintf*(3) and reads input from the stream pointer *stream* using a variable argument list of pointers (see *stdarg*(3). The **vscanf**() function is analogous to *vprintf*(3) and reads from the standard input.

RETURN VALUE

On success, these functions return the number of input items successfully matched and assigned; this can be fewer than provided for, or even zero, in the event of an early matching failure.

The value **EOF** is returned if the end of input is reached before either the first successful conversion or a matching failure occurs. **EOF** is also returned if a read error occurs, in which case the error indicator for the stream (see *ferror*(3)) is set, and *errno* is set to indicate the error.

ERRORS

EAGAIN
: The file descriptor underlying *stream* is marked nonblocking, and the read operation would block.

EBADF
: The file descriptor underlying *stream* is invalid, or not open for reading.

EILSEQ
: Input byte sequence does not form a valid character.

EINTR
: The read operation was interrupted by a signal; see *signal*(7).

EINVAL
: Not enough arguments; or *format* is NULL.

ENOMEM
: Out of memory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
scanf(), **fscanf**(), **vscanf**(), **vfscanf**()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

CAVEATS

These functions make it difficult to distinguish newlines from other white space, This is especially problematic with line-buffered input, like the standard input stream.

These functions can’t report errors after the last non-suppressed conversion specification.

BUGS

It is impossible to accurately know how many characters these functions have consumed from the input stream, since they only report the number of successful conversions. For example, if the input is "123\n a", *scanf("%d %d", &a, &b)* will consume the digits, the newline, and the space, but not the letter a. This makes it difficult to recover from invalid input.

NAME

sched_getcpu − determine CPU on which the calling thread is running

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sched.h>

int sched_getcpu(void);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sched_getcpu():
Since glibc 2.14:
_GNU_SOURCE
Before glibc 2.14:
_BSD_SOURCE || _SVID_SOURCE
/* _GNU_SOURCE also suffices */

DESCRIPTION

sched_getcpu() returns the number of the CPU on which the calling thread is currently executing.

RETURN VALUE

On success, **sched_getcpu**() returns a nonnegative CPU number. On error, −1 is returned and *errno* is set to indicate the error.

ERRORS

ENOSYS
This kernel does not implement *getcpu*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sched_getcpu()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.6.

NOTES

The call

```
cpu = sched_getcpu();
```

is equivalent to the following *getcpu*(2) call:

```
int c, s;
s = getcpu(&c, NULL);
cpu = (s == -1) ? s : c;
```

SEE ALSO

getcpu(2), *sched*(7)

NAME

seekdir − set the position of the next readdir() call in the directory stream.

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <dirent.h>

void seekdir(DIR *****dirp*, long** *loc***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

seekdir():
_XOPEN_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **seekdir**() function sets the location in the directory stream from which the next *readdir*(2) call will start. The *loc* argument should be a value returned by a previous call to *telldir*(3).

RETURN VALUE

The **seekdir**() function returns no value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
seekdir()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.3BSD.

CAVEATS

Up to glibc 2.1.1, the type of the *loc* argument was *off_t*. POSIX.1-2001 specifies *long*, and this is the type used since glibc 2.1.2. See *telldir*(3) for information on why you should be careful in making any assumptions about the value in this argument.

SEE ALSO

NAME

sem_close − close a named semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <semaphore.h>

int sem_close(sem_t ****sem*);**

DESCRIPTION

sem_close() closes the named semaphore referred to by *sem*, allowing any resources that the system has allocated to the calling process for this semaphore to be freed.

RETURN VALUE

On success **sem_close**() returns 0; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EINVAL

sem is not a valid semaphore.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sem_close()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

All open named semaphores are automatically closed on process termination, or upon *execve*(2).

SEE ALSO

sem_getvalue(3), *sem_open*(3), *sem_post*(3), *sem_unlink*(3), *sem_wait*(3), *sem_overview*(7)

NAME

sem_destroy − destroy an unnamed semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <semaphore.h>

int sem_destroy(sem_t *_sem_);

DESCRIPTION

sem_destroy() destroys the unnamed semaphore at the address pointed to by *sem*.

Only a semaphore that has been initialized by *sem_init*(3) should be destroyed using **sem_destroy**().

Destroying a semaphore that other processes or threads are currently blocked on (in *sem_wait*(3)) produces undefined behavior.

Using a semaphore that has been destroyed produces undefined results, until the semaphore has been reinitialized using *sem_init*(3).

RETURN VALUE

sem_destroy() returns 0 on success; on error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL

sem is not a valid semaphore.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sem_destroy()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

An unnamed semaphore should be destroyed with **sem_destroy**() before the memory in which it is located is deallocated. Failure to do this can result in resource leaks on some implementations.

SEE ALSO

sem_init(3), *sem_post*(3), *sem_wait*(3), *sem_overview*(7)

NAME

sem_getvalue − get the value of a semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <semaphore.h>

int sem_getvalue(sem_t *restrict *sem***, int *restrict** *sval***);**

DESCRIPTION

sem_getvalue() places the current value of the semaphore pointed to *sem* into the integer pointed to by *sval*.

If one or more processes or threads are blocked waiting to lock the semaphore with *sem_wait*(3), POSIX.1 permits two possibilities for the value returned in *sval*: either 0 is returned; or a negative number whose absolute value is the count of the number of processes and threads currently blocked in *sem_wait*(3). Linux adopts the former behavior.

RETURN VALUE

sem_getvalue() returns 0 on success; on error, −1 is returned and *errno* is set to indicate the error.

ERRORS

EINVAL

sem is not a valid semaphore. (The glibc implementation currently does not check whether *sem* is valid.)

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sem_getvalue()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

The value of the semaphore may already have changed by the time **sem_getvalue**() returns.

SEE ALSO

sem_post(3), *sem_wait*(3), *sem_overview*(7)

NAME

sem_init − initialize an unnamed semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <semaphore.h>

int sem_init(sem_t ****sem*, int** *pshared***, unsigned int** *value***);**

DESCRIPTION

sem_init() initializes the unnamed semaphore at the address pointed to by *sem*. The *value* argument specifies the initial value for the semaphore.

The *pshared* argument indicates whether this semaphore is to be shared between the threads of a process, or between processes.

If *pshared* has the value 0, then the semaphore is shared between the threads of a process, and should be located at some address that is visible to all threads (e.g., a global variable, or a variable allocated dynamically on the heap).

If *pshared* is nonzero, then the semaphore is shared between processes, and should be located in a region of shared memory (see *shm_open*(3), *mmap*(2), and *shmget*(2)). (Since a child created by *fork*(2) inherits its parent's memory mappings, it can also access the semaphore.) Any process that can access the shared memory region can operate on the semaphore using *sem_post*(3), *sem_wait*(3), and so on.

Initializing a semaphore that has already been initialized results in undefined behavior.

RETURN VALUE

sem_init() returns 0 on success; on error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL

value exceeds **SEM_VALUE_MAX**.

ENOSYS

pshared is nonzero, but the system does not support process-shared semaphores (see *sem_overview*(7)).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sem_init()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

Bizarrely, POSIX.1-2001 does not specify the value that should be returned by a successful call to **sem_init**(). POSIX.1-2008 rectifies this, specifying the zero return on success.

EXAMPLES

See *shm_open*(3) and *sem_wait*(3).

SEE ALSO

sem_destroy(3), *sem_post*(3), *sem_wait*(3), *sem_overview*(7)

NAME

sem_open − initialize and open a named semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <fcntl.h>          /* For O_* constants */
#include <sys/stat.h>       /* For mode constants */
#include <semaphore.h>

sem_t *sem_open(const char *name, int oflag);
sem_t *sem_open(const char *name, int oflag,
                mode_t mode, unsigned int value);
```

DESCRIPTION

sem_open() creates a new POSIX semaphore or opens an existing semaphore. The semaphore is identified by *name*. For details of the construction of *name*, see *sem_overview*(7).

The *oflag* argument specifies flags that control the operation of the call. (Definitions of the flags values can be obtained by including <*fcntl.h*>.) If **O_CREAT** is specified in *oflag*, then the semaphore is created if it does not already exist. The owner (user ID) of the semaphore is set to the effective user ID of the calling process. The group ownership (group ID) is set to the effective group ID of the calling process. If both **O_CREAT** and **O_EXCL** are specified in *oflag*, then an error is returned if a semaphore with the given *name* already exists.

If **O_CREAT** is specified in *oflag*, then two additional arguments must be supplied. The *mode* argument specifies the permissions to be placed on the new semaphore, as for *open*(2). (Symbolic definitions for the permissions bits can be obtained by including <*sys/stat.h*>.) The permissions settings are masked against the process umask. Both read and write permission should be granted to each class of user that will access the semaphore. The *value* argument specifies the initial value for the new semaphore. If **O_CREAT** is specified, and a semaphore with the given *name* already exists, then *mode* and *value* are ignored.

RETURN VALUE

On success, **sem_open**() returns the address of the new semaphore; this address is used when calling other semaphore-related functions. On error, **sem_open**() returns **SEM_FAILED**, with *errno* set to indicate the error.

ERRORS

EACCES
: The semaphore exists, but the caller does not have permission to open it.

EEXIST
: Both **O_CREAT** and **O_EXCL** were specified in *oflag*, but a semaphore with this *name* already exists.

EINVAL
: *value* was greater than **SEM_VALUE_MAX**.

EINVAL
: *name* consists of just "/", followed by no other characters.

EMFILE
: The per-process limit on the number of open file descriptors has been reached.

ENAMETOOLONG
: *name* was too long.

ENFILE
: The system-wide limit on the total number of open files has been reached.

ENOENT
: The **O_CREAT** flag was not specified in *oflag* and no semaphore with this *name* exists; or, **O_CREAT** was specified, but *name* wasn't well formed.

ENOMEM
Insufficient memory.

ATTRIBUTES

NAME

sem_post − unlock a semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <semaphore.h>

int sem_post(sem_t *****sem*);**

DESCRIPTION

sem_post() increments (unlocks) the semaphore pointed to by *sem*. If the semaphore's value consequently becomes greater than zero, then another process or thread blocked in a *sem_wait*(3) call will be woken up and proceed to lock the semaphore.

RETURN VALUE

sem_post() returns 0 on success; on error, the value of the semaphore is left unchanged, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EINVAL

sem is not a valid semaphore.

EOVERFLOW

The maximum allowable value for a semaphore would be exceeded.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sem_post()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

sem_post() is async-signal-safe: it may be safely called within a signal handler.

EXAMPLES

See *sem_wait*(3) and *shm_open*(3).

SEE ALSO

NAME

sem_unlink − remove a named semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

#include <semaphore.h>

int sem_unlink(const char *_name_);

DESCRIPTION

sem_unlink() removes the named semaphore referred to by *name*. The semaphore name is removed immediately. The semaphore is destroyed once all other processes that have the semaphore open close it.

RETURN VALUE

On success **sem_unlink**() returns 0; on error, −1 is returned, with *errno* set to indicate the error.

ERRORS

EACCES
The caller does not have permission to unlink this semaphore.

ENAMETOOLONG
name was too long.

ENOENT
There is no semaphore with the given *name*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

HISTORY

POSIX.1-2001.

SEE ALSO

sem_getvalue(3), *sem_open*(3), *sem_post*(3), *sem_wait*(3), *sem_overview*(7)

NAME

sem_wait, sem_timedwait, sem_trywait − lock a semaphore

LIBRARY

POSIX threads library (*libpthread*, *−lpthread*)

SYNOPSIS

```
#include <semaphore.h>

int sem_wait(sem_t *sem);
int sem_trywait(sem_t *sem);
int sem_timedwait(sem_t *restrict sem,
                  const struct timespec *restrict abs_timeout);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sem_timedwait():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

sem_wait() decrements (locks) the semaphore pointed to by *sem*. If the semaphore's value is greater than zero, then the decrement proceeds, and the function returns, immediately. If the semaphore currently has the value zero, then the call blocks until either it becomes possible to perform the decrement (i.e., the semaphore value rises above zero), or a signal handler interrupts the call.

sem_trywait() is the same as **sem_wait**(), except that if the decrement cannot be immediately performed, then call returns an error (*errno* set to **EAGAIN**) instead of blocking.

sem_timedwait() is the same as **sem_wait**(), except that *abs_timeout* specifies a limit on the amount of time that the call should block if the decrement cannot be immediately performed. The *abs_timeout* argument points to a *timespec*(3) structure that specifies an absolute timeout in seconds and nanoseconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC).

If the timeout has already expired by the time of the call, and the semaphore could not be locked immediately, then **sem_timedwait**() fails with a timeout error (*errno* set to **ETIMEDOUT**).

If the operation can be performed immediately, then **sem_timedwait**() never fails with a timeout error, regardless of the value of *abs_timeout*. Furthermore, the validity of *abs_timeout* is not checked in this case.

RETURN VALUE

All of these functions return 0 on success; on error, the value of the semaphore is left unchanged, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EAGAIN
(**sem_trywait**()) The operation could not be performed without blocking (i.e., the semaphore currently has the value zero).

EINTR
The call was interrupted by a signal handler; see *signal*(7).

EINVAL
sem is not a valid semaphore.

EINVAL
(**sem_timedwait**()) The value of *abs_timeout.tv_nsecs* is less than 0, or greater than or equal to 1000 million.

ETIMEDOUT
(**sem_timedwait**()) The call timed out before the semaphore could be locked.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sem_wait(), **sem_trywait**(), **sem_timedwait**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

The (somewhat trivial) program shown below operates on an unnamed semaphore. The program expects two command-line arguments. The first argument specifies a seconds value that is used to set an alarm timer to generate a **SIGALRM** signal. This handler performs a *sem_post*(3) to increment the semaphore that is being waited on in *main()* using **sem_timedwait**(). The second command-line argument specifies the length of the timeout, in seconds, for **sem_timedwait**(). The following shows what happens on two different runs of the program:

```
$ ./a.out 2 3
About to call sem_timedwait()
sem_post() from handler
sem_timedwait() succeeded
$ ./a.out 2 1
About to call sem_timedwait()
sem_timedwait() timed out
```

Program source

```
#include <errno.h>
#include <semaphore.h>
#include <signal.h>
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
#include <unistd.h>

#include <assert.h>

sem_t sem;

#define handle_error(msg) \
    do { perror(msg); exit(EXIT_FAILURE); } while (0)

static void
handler(int sig)
{
    write(STDOUT_FILENO, "sem_post() from handler\n", 24);
    if (sem_post(&sem) == -1) {
        write(STDERR_FILENO, "sem_post() failed\n", 18);
        _exit(EXIT_FAILURE);
    }
}

int
main(int argc, char *argv[])
{
    struct sigaction sa;
    struct timespec ts;
    int s;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <alarm-secs> <wait-secs>\n",
                argv[0]);
        exit(EXIT_FAILURE);
    }
```

```
        if (sem_init(&sem, 0, 0) == -1)
            handle_error("sem_init");

        /* Establish SIGALRM handler; set alarm timer using argv[1]. */

        sa.sa_handler = handler;
        sigemptyset(&sa.sa_mask);
        sa.sa_flags = 0;
        if (sigaction(SIGALRM, &sa, NULL) == -1)
            handle_error("sigaction");

        alarm(atoi(argv[1]));

        /* Calculate relative interval as current time plus
           number of seconds given argv[2]. */

        if (clock_gettime(CLOCK_REALTIME, &ts) == -1)
            handle_error("clock_gettime");

        ts.tv_sec += atoi(argv[2]);

        printf("%s() about to call sem_timedwait()\n", __func__);
        while ((s = sem_timedwait(&sem, &ts)) == -1 && errno == EINTR)
            continue;       /* Restart if interrupted by handler. */

        /* Check what happened. */

        if (s == -1) {
            if (errno == ETIMEDOUT)
                printf("sem_timedwait() timed out\n");
            else
                perror("sem_timedwait");
        } else
            printf("sem_timedwait() succeeded\n");

        exit((s == 0) ? EXIT_SUCCESS : EXIT_FAILURE);
    }
```

NAME

setaliasent, endaliasent, getaliasent, getaliasent_r, getaliasbyname, getaliasbyname_r − read an alias entry

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <aliases.h>

void setaliasent(void);
void endaliasent(void);

struct aliasent *getaliasent(void);
int getaliasent_r(struct aliasent *restrict result,
                  char buffer[restrict .buflen], size_t buflen,
                  struct aliasent **restrict res);

struct aliasent *getaliasbyname(const char *name);
int getaliasbyname_r(const char *restrict name,
                  struct aliasent *restrict result,
                  char buffer[restrict .buflen], size_t buflen,
                  struct aliasent **restrict res);
```

DESCRIPTION

One of the databases available with the Name Service Switch (NSS) is the aliases database, that contains mail aliases. (To find out which databases are supported, try *getent −−help*.) Six functions are provided to access the aliases database.

The **getaliasent**() function returns a pointer to a structure containing the group information from the aliases database. The first time it is called it returns the first entry; thereafter, it returns successive entries.

The **setaliasent**() function rewinds the file pointer to the beginning of the aliases database.

The **endaliasent**() function closes the aliases database.

getaliasent_r() is the reentrant version of the previous function. The requested structure is stored via the first argument but the programmer needs to fill the other arguments also. Not providing enough space causes the function to fail.

The function **getaliasbyname**() takes the name argument and searches the aliases database. The entry is returned as a pointer to a *struct aliasent*.

getaliasbyname_r() is the reentrant version of the previous function. The requested structure is stored via the second argument but the programmer needs to fill the other arguments also. Not providing enough space causes the function to fail.

The *struct aliasent* is defined in <*aliases.h*>:

```
struct aliasent {
    char    *alias_name;             /* alias name */
    size_t   alias_members_len;
    char   **alias_members;          /* alias name list */
    int      alias_local;
};
```

RETURN VALUE

The functions **getaliasent_r**() and **getaliasbyname_r**() return a nonzero value on error.

FILES

The default alias database is the file */etc/aliases*. This can be changed in the */etc/nsswitch.conf* file.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setaliasent(), **endaliasent**(), **getaliasent_r**(), **getaliasbyname_r**()	Thread safety	MT-Safe locale
getaliasent(), **getaliasbyname**()	Thread safety	MT-Unsafe

STANDARDS

GNU.

HISTORY

The NeXT system has similar routines:

```
#include <aliasdb.h>

void alias_setent(void);
void alias_endent(void);
alias_ent *alias_getent(void);
alias_ent *alias_getbyname(char *name);
```

EXAMPLES

The following example compiles with *gcc example.c −o example*. It will dump all names in the alias database.

```
#include <aliases.h>
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>

int
main(void)
{
    struct aliasent *al;

    setaliasent();
    for (;;) {
        al = getaliasent();
        if (al == NULL)
            break;
        printf("Name: %s\n", al->alias_name);
    }
    if (errno) {
        perror("reading alias");
        exit(EXIT_FAILURE);
    }
    endaliasent();
    exit(EXIT_SUCCESS);
}
```

NAME

setbuf, setbuffer, setlinebuf, setvbuf − stream buffering operations

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int setvbuf(FILE *restrict stream, char buf[restrict .size],
        int mode, size_t size);

void setbuf(FILE *restrict stream, char *restrict buf);
void setbuffer(FILE *restrict stream, char buf[restrict .size],
        size_t size);
void setlinebuf(FILE *stream);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

setbuffer(), **setlinebuf**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The three types of buffering available are unbuffered, block buffered, and line buffered. When an output stream is unbuffered, information appears on the destination file or terminal as soon as written; when it is block buffered, many characters are saved up and written as a block; when it is line buffered, characters are saved up until a newline is output or input is read from any stream attached to a terminal device (typically *stdin*). The function *fflush*(3) may be used to force the block out early. (See *fclose*(3).)

Normally all files are block buffered. If a stream refers to a terminal (as *stdout* normally does), it is line buffered. The standard error stream *stderr* is always unbuffered by default.

The **setvbuf**() function may be used on any open stream to change its buffer. The *mode* argument must be one of the following three macros:

_IONBF
unbuffered

_IOLBF
line buffered

_IOFBF
fully buffered

Except for unbuffered files, the *buf* argument should point to a buffer at least *size* bytes long; this buffer will be used instead of the current buffer. If the argument *buf* is NULL, only the mode is affected; a new buffer will be allocated on the next read or write operation. The **setvbuf**() function may be used only after opening a stream and before any other operations have been performed on it.

The other three calls are, in effect, simply aliases for calls to **setvbuf**(). The **setbuf**() function is exactly equivalent to the call

```
setvbuf(stream, buf, buf ? _IOFBF : _IONBF, BUFSIZ);
```

The **setbuffer**() function is the same, except that the size of the buffer is up to the caller, rather than being determined by the default **BUFSIZ**. The **setlinebuf**() function is exactly equivalent to the call:

```
setvbuf(stream, NULL, _IOLBF, 0);
```

RETURN VALUE

The function **setvbuf**() returns 0 on success. It returns nonzero on failure (*mode* is invalid or the request cannot be honored). It may set *errno* on failure.

The other functions do not return a value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setbuf(), **setbuffer**(), **setlinebuf**(), **setvbuf**()	Thread safety	MT-Safe

STANDARDS

setbuf()
setvbuf()
C11, POSIX.1-2008.

HISTORY

setbuf()
setvbuf()
C89, POSIX.1-2001.

CAVEATS

POSIX notes that the value of *errno* is unspecified after a call to **setbuf**() and further notes that, since the value of *errno* is not required to be unchanged after a successful call to **setbuf**(), applications should instead use **setvbuf**() in order to detect errors.

BUGS

You must make sure that the space that *buf* points to still exists by the time *stream* is closed, which also happens at program termination. For example, the following is invalid:

```
#include <stdio.h>

int
main(void)
{
    char buf[BUFSIZ];

    setbuf(stdout, buf);
    printf("Hello, world!\n");
    return 0;
}
```

SEE ALSO

stdbuf (1), *fclose*(3), *fflush*(3), *fopen*(3), *fread*(3), *malloc*(3), *printf*(3), *puts*(3)

NAME

setenv − change or add an environment variable

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int setenv(const char *name, const char *value, int overwrite);
int unsetenv(const char *name);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

setenv(), **unsetenv**():

```
_POSIX_C_SOURCE >= 200112L
    || /* glibc <= 2.19: */ _BSD_SOURCE
```

DESCRIPTION

The **setenv**() function adds the variable *name* to the environment with the value *value*, if *name* does not already exist. If *name* does exist in the environment, then its value is changed to *value* if *overwrite* is nonzero; if *overwrite* is zero, then the value of *name* is not changed (and **setenv**() returns a success status). This function makes copies of the strings pointed to by *name* and *value* (by contrast with *putenv*(3)).

The **unsetenv**() function deletes the variable *name* from the environment. If *name* does not exist in the environment, then the function succeeds, and the environment is unchanged.

RETURN VALUE

setenv() and **unsetenv**() functions return zero on success, or −1 on error, with *errno* set to indicate the error.

ERRORS

EINVAL
: *name* is NULL, points to a string of length 0, or contains an '=' character.

ENOMEM
: Insufficient memory to add a new variable to the environment.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setenv(), **unsetenv**()	Thread safety	MT-Unsafe const:env

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.3BSD.

Prior to glibc 2.2.2, **unsetenv**() was prototyped as returning *void*; more recent glibc versions follow the POSIX.1-compliant prototype shown in the SYNOPSIS.

CAVEATS

POSIX.1 does not require **setenv**() or **unsetenv**() to be reentrant.

BUGS

POSIX.1 specifies that if *name* contains an '=' character, then **setenv**() should fail with the error **EINVAL**; however, versions of glibc before glibc 2.3.4 allowed an '=' sign in *name*.

clearenv(3), *getenv*(3), *putenv*(3), *environ*(7)

NAME

__setfpucw − set FPU control word on i386 architecture (obsolete)

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <i386/fpu_control.h>

[[deprecated]] void __setfpucw(unsigned short *control_word***);**

DESCRIPTION

__setfpucw() transfers *control_word* to the registers of the FPU (floating-point unit) on the i386 architecture. This was used to control floating-point precision, rounding and floating-point exceptions.

STANDARDS

GNU.

HISTORY

Removed in glibc 2.1.

NOTES

There are new functions from C99, with prototypes in <*fenv.h*>, to control FPU rounding modes, like *fegetround*(3), *fesetround*(3), and the floating-point environment, like *fegetenv*(3), *feholdexcept*(3), *fesetenv*(3), *feupdateenv*(3), and FPU exception handling, like *feclearexcept*(3), *fegetexceptflag*(3), *feraiseexcept*(3), *fesetexceptflag*(3), and *fetestexcept*(3).

If direct access to the FPU control word is still needed, the **_FPU_GETCW** and **_FPU_SETCW** macros from <*fpu_control.h*> can be used.

EXAMPLES

__setfpucw(0x1372)

Set FPU control word on the i386 architecture to

- extended precision
- rounding to nearest
- exceptions on overflow, zero divide and NaN

SEE ALSO

feclearexcept(3)

<*fpu_control.h*>

NAME

setjmp, sigsetjmp, longjmp, siglongjmp − performing a nonlocal goto

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <setjmp.h>

int setjmp(jmp_buf env);
int sigsetjmp(sigjmp_buf env, int savesigs);

[[noreturn]] void longjmp(jmp_buf env, int val);
[[noreturn]] void siglongjmp(sigjmp_buf env, int val);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

setjmp(): see NOTES.

sigsetjmp():
_POSIX_C_SOURCE

DESCRIPTION

The functions described on this page are used for performing "nonlocal gotos": transferring execution from one function to a predetermined location in another function. The **setjmp**() function dynamically establishes the target to which control will later be transferred, and **longjmp**() performs the transfer of execution.

The **setjmp**() function saves various information about the calling environment (typically, the stack pointer, the instruction pointer, possibly the values of other registers and the signal mask) in the buffer *env* for later use by **longjmp**(). In this case, **setjmp**() returns 0.

The **longjmp**() function uses the information saved in *env* to transfer control back to the point where **setjmp**() was called and to restore ("rewind") the stack to its state at the time of the **setjmp**() call. In addition, and depending on the implementation (see NOTES), the values of some other registers and the process signal mask may be restored to their state at the time of the **setjmp**() call.

Following a successful **longjmp**(), execution continues as if **setjmp**() had returned for a second time. This "fake" return can be distinguished from a true **setjmp**() call because the "fake" return returns the value provided in *val*. If the programmer mistakenly passes the value 0 in *val*, the "fake" return will instead return 1.

sigsetjmp() and siglongjmp()

sigsetjmp() and **siglongjmp**() also perform nonlocal gotos, but provide predictable handling of the process signal mask.

If, and only if, the *savesigs* argument provided to **sigsetjmp**() is nonzero, the process's current signal mask is saved in *env* and will be restored if a **siglongjmp**() is later performed with this *env*.

RETURN VALUE

setjmp() and **sigsetjmp**() return 0 when called directly; on the "fake" return that occurs after **longjmp**() or **siglongjmp**(), the nonzero value specified in *val* is returned.

The **longjmp**() or **siglongjmp**() functions do not return.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setjmp(), **sigsetjmp**()	Thread safety	MT-Safe
longjmp(), **siglongjmp**()	Thread safety	MT-Safe

STANDARDS

setjmp()
longjmp()
C11, POSIX.1-2008.

sigsetjmp()

siglongjmp()
POSIX.1-2008.

HISTORY

setjmp()
longjmp()
POSIX.1-2001, C89.

sigsetjmp()
siglongjmp()
POSIX.1-2001.

POSIX does not specify whether **setjmp**() will save the signal mask (to be later restored during *longjmp*())In System V it will not. In 4.3BSD it will, and there is a function **_setjmp**() that will not. The behavior under Linux depends on the glibc version and the setting of feature test macros. Before glibc 2.19, **setjmp**() follows the System V behavior by default, but the BSD behavior is provided if the **_BSD_SOURCE** feature test macro is explicitly defined and none of **_POSIX_SOURCE**, **_POSIX_C_SOURCE**, **_XOPEN_SOURCE**, **_GNU_SOURCE**, or **_SVID_SOURCE** is defined. Since glibc 2.19, <*setjmp.h*> exposes only the System V version of **setjmp**(). Programs that need the BSD semantics should replace calls to **setjmp**() with calls to **sigsetjmp**() with a nonzero *savesigs* argument.

NOTES

setjmp() and **longjmp**() can be useful for dealing with errors inside deeply nested function calls or to allow a signal handler to pass control to a specific point in the program, rather than returning to the point where the handler interrupted the main program. In the latter case, if you want to portably save and restore signal masks, use **sigsetjmp**() and **siglongjmp**(). See also the discussion of program readability below.

CAVEATS

The compiler may optimize variables into registers, and **longjmp**() may restore the values of other registers in addition to the stack pointer and program counter. Consequently, the values of automatic variables are unspecified after a call to **longjmp**() if they meet all the following criteria:

- they are local to the function that made the corresponding **setjmp**() call;
- their values are changed between the calls to **setjmp**() and **longjmp**(); and
- they are not declared as *volatile*.

Analogous remarks apply for **siglongjmp**().

Nonlocal gotos and program readability

While it can be abused, the traditional C "goto" statement at least has the benefit that lexical cues (the goto statement and the target label) allow the programmer to easily perceive the flow of control. Nonlocal gotos provide no such cues: multiple **setjmp**() calls might employ the same *jmp_buf* variable so that the content of the variable may change over the lifetime of the application. Consequently, the programmer may be forced to perform detailed reading of the code to determine the dynamic target of a particular **longjmp**() call. (To make the programmer's life easier, each **setjmp**() call should employ a unique *jmp_buf* variable.)

Adding further difficulty, the **setjmp**() and **longjmp**() calls may not even be in the same source code module.

In summary, nonlocal gotos can make programs harder to understand and maintain, and an alternative should be used if possible.

Undefined Behavior

If the function which called **setjmp**() returns before **longjmp**() is called, the behavior is undefined. Some kind of subtle or unsubtle chaos is sure to result.

If, in a multithreaded program, a **longjmp**() call employs an *env* buffer that was initialized by a call to **setjmp**() in a different thread, the behavior is undefined.

POSIX.1-2008 Technical Corrigendum 2 adds **longjmp**() and **siglongjmp**() to the list of async-signal-safe functions. However, the standard recommends avoiding the use of these functions from signal handlers and goes on to point out that if these functions are called from a signal handler that interrupted a call to a non-async-signal-safe function (or some equivalent, such as the steps equivalent to *exit*(3)

that occur upon a return from the initial call to *main*()), the behavior is undefined if the program subsequently makes a call to a non-async-signal-safe function. The only way of avoiding undefined behavior is to ensure one of the following:

- After long jumping from the signal handler, the program does not call any non-async-signal-safe functions and does not return from the initial call to *main*().
- Any signal whose handler performs a long jump must be blocked during *every* call to a non-async-signal-safe function and no non-async-signal-safe functions are called after returning from the initial call to *main*().

NAME

setlocale − set the current locale

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <locale.h>

char *setlocale(int *category***, const char *** *locale***);**

DESCRIPTION

The **setlocale**() function is used to set or query the program's current locale.

If *locale* is not NULL, the program's current locale is modified according to the arguments. The argument *category* determines which parts of the program's current locale should be modified.

Category	Governs
LC_ALL	All of the locale
LC_ADDRESS	Formatting of addresses and geography-related items (*)
LC_COLLATE	String collation
LC_CTYPE	Character classification
LC_IDENTIFICATION	Metadata describing the locale (*)
LC_MEASUREMENT	Settings related to measurements (metric versus US customary) (*)
LC_MESSAGES	Localizable natural-language messages
LC_MONETARY	Formatting of monetary values
LC_NAME	Formatting of salutations for persons (*)
LC_NUMERIC	Formatting of nonmonetary numeric values
LC_PAPER	Settings related to the standard paper size (*)
LC_TELEPHONE	Formats to be used with telephone services (*)
LC_TIME	Formatting of date and time values

The categories marked with an asterisk in the above table are GNU extensions. For further information on these locale categories, see *locale*(7).

The argument *locale* is a pointer to a character string containing the required setting of *category*. Such a string is either a well-known constant like "C" or "da_DK" (see below), or an opaque string that was returned by another call of **setlocale**().

If *locale* is an empty string, **""**, each part of the locale that should be modified is set according to the environment variables. The details are implementation-dependent. For glibc, first (regardless of *category*), the environment variable **LC_ALL** is inspected, next the environment variable with the same name as the category (see the table above), and finally the environment variable **LANG**. The first existing environment variable is used. If its value is not a valid locale specification, the locale is unchanged, and **setlocale**() returns NULL.

The locale **"C"** or **"POSIX"** is a portable locale; it exists on all conforming systems.

A locale name is typically of the form *language*[*_territory*][*.codeset*][*@modifier*], where *language* is an ISO 639 language code, *territory* is an ISO 3166 country code, and *codeset* is a character set or encoding identifier like **ISO−8859−1** or **UTF-8**. For a list of all supported locales, try "locale −a" (see *locale*(1)).

If *locale* is NULL, the current locale is only queried, not modified.

On startup of the main program, the portable **"C"** locale is selected as default. A program may be made portable to all locales by calling:

```
setlocale(LC_ALL, "");
```

after program initialization, and then:

- using the values returned from a *localeconv*(3) call for locale-dependent information;
- using the multibyte and wide character functions for text processing if **MB_CUR_MAX > 1**;
- using *strcoll*(3) and *strxfrm*(3) to compare strings; and

- using *wcscoll*(3) and *wcsxfrm*(3) to compare wide-character strings.

RETURN VALUE

A successful call to **setlocale**() returns an opaque string that corresponds to the locale set. This string may be allocated in static storage. The string returned is such that a subsequent call with that string and its associated category will restore that part of the process's locale. The return value is NULL if the request cannot be honored.

NAME

setlogmask − set log priority mask

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <syslog.h>

int setlogmask(int *mask***);**

DESCRIPTION

A process has a log priority mask that determines which calls to *syslog*(3) may be logged. All other calls will be ignored. Logging is enabled for the priorities that have the corresponding bit set in *mask*. The initial mask is such that logging is enabled for all priorities.

The **setlogmask**() function sets this logmask for the calling process, and returns the previous mask. If the *mask* argument is **0**, the current logmask is not modified.

The eight priorities are **LOG_EMERG**, **LOG_ALERT**, **LOG_CRIT**, **LOG_ERR**, **LOG_WARNING**, **LOG_NOTICE**, **LOG_INFO**, and **LOG_DEBUG**. The bit corresponding to a priority *p* is *LOG_MASK(p)*. Some systems also provide a macro *LOG_UPTO(p)* for the mask of all priorities in the above list up to and including *p*.

RETURN VALUE

This function returns the previous log priority mask.

ERRORS

None.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setlogmask()	Thread safety	MT-Unsafe race:LogMask

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

LOG_UPTO() will be included in the next release of the POSIX specification (Issue 8).

NAME

setnetgrent, endnetgrent, getnetgrent, getnetgrent_r, innetgr − handle network group entries

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <netdb.h>

int setnetgrent(const char *netgroup);
void endnetgrent(void);

int getnetgrent(char **restrict host,
        char **restrict user, char **restrict domain);
int getnetgrent_r(char **restrict host,
        char **restrict user, char **restrict domain,
        char buf[restrict .buflen], size_t buflen);

int innetgr(const char *netgroup, const char *host,
        const char *user, const char *domain);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

setnetgrent(), **endnetgrent**(), **getnetgrent**(), **getnetgrent_r**(), **innetgr**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The *netgroup* is a SunOS invention. A netgroup database is a list of string triples (*hostname*, *username*, *domainname*) or other netgroup names. Any of the elements in a triple can be empty, which means that anything matches. The functions described here allow access to the netgroup databases. The file */etc/nsswitch.conf* defines what database is searched.

The **setnetgrent**() call defines the netgroup that will be searched by subsequent **getnetgrent**() calls. The **getnetgrent**() function retrieves the next netgroup entry, and returns pointers in *host*, *user*, *domain*. A null pointer means that the corresponding entry matches any string. The pointers are valid only as long as there is no call to other netgroup-related functions. To avoid this problem you can use the GNU function **getnetgrent_r**() that stores the strings in the supplied buffer. To free all allocated buffers use **endnetgrent**().

In most cases you want to check only if the triplet (*hostname*, *username*, *domainname*) is a member of a netgroup. The function **innetgr**() can be used for this without calling the above three functions. Again, a null pointer is a wildcard and matches any string. The function is thread-safe.

RETURN VALUE

These functions return 1 on success and 0 for failure.

FILES

/etc/netgroup
/etc/nsswitch.conf

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
setnetgrent(), **getnetgrent_r**(), **innetgr**()	Thread safety	MT-Unsafe race:netgrent locale
endnetgrent()	Thread safety	MT-Unsafe race:netgrent
getnetgrent()	Thread safety	MT-Unsafe race:netgrent race:netgrentbuf locale

In the above table, *netgrent* in *race:netgrent* signifies that if any of the functions **setnetgrent**(), **getnetgrent_r**(), **innetgr**(), **getnetgrent**(), or **endnetgrent**() are used in parallel in different threads of a program, then data races could occur.

VERSIONS

In the BSD implementation, **setnetgrent**() returns void.

STANDARDS

None.

HISTORY

setnetgrent(), **endnetgrent**(), **getnetgrent**(), and **innetgr**() are available on most UNIX systems. **getnetgrent_r**() is not widely available on other systems.

sethostent(3), *setprotoent*(3), *setservent*(3)

NAME

shm_open, shm_unlink − create/open or unlink POSIX shared memory objects

LIBRARY

Real-time library (*librt*, *−lrt*)

SYNOPSIS

```
#include <sys/mman.h>
#include <sys/stat.h>        /* For mode constants */
#include <fcntl.h>           /* For O_* constants */

int shm_open(const char *name, int oflag, mode_t mode);
int shm_unlink(const char *name);
```

DESCRIPTION

shm_open() creates and opens a new, or opens an existing, POSIX shared memory object. A POSIX shared memory object is in effect a handle which can be used by unrelated processes to *mmap*(2) the same region of shared memory. The **shm_unlink**() function performs the converse operation, removing an object previously created by **shm_open**().

The operation of **shm_open**() is analogous to that of *open*(2). *name* specifies the shared memory object to be created or opened. For portable use, a shared memory object should be identified by a name of the form */somename*; that is, a null-terminated string of up to **NAME_MAX** (i.e., 255) characters consisting of an initial slash, followed by one or more characters, none of which are slashes.

oflag is a bit mask created by ORing together exactly one of **O_RDONLY** or **O_RDWR** and any of the other flags listed here:

O_RDONLY
: Open the object for read access. A shared memory object opened in this way can be *mmap*(2)ed only for read (**PROT_READ**) access.

O_RDWR
: Open the object for read-write access.

O_CREAT
: Create the shared memory object if it does not exist. The user and group ownership of the object are taken from the corresponding effective IDs of the calling process, and the object's permission bits are set according to the low-order 9 bits of *mode*, except that those bits set in the process file mode creation mask (see *umask*(2)) are cleared for the new object. A set of macro constants which can be used to define *mode* is listed in *open*(2). (Symbolic definitions of these constants can be obtained by including <*sys/stat.h*>.)

  A new shared memory object initially has zero length—the size of the object can be set using *ftruncate*(2). The newly allocated bytes of a shared memory object are automatically initialized to 0.

O_EXCL
: If **O_CREAT** was also specified, and a shared memory object with the given *name* already exists, return an error. The check for the existence of the object, and its creation if it does not exist, are performed atomically.

O_TRUNC
: If the shared memory object already exists, truncate it to zero bytes.

Definitions of these flag values can be obtained by including <*fcntl.h*>.

On successful completion **shm_open**() returns a new file descriptor referring to the shared memory object. This file descriptor is guaranteed to be the lowest-numbered file descriptor not previously opened within the process. The **FD_CLOEXEC** flag (see *fcntl*(2)) is set for the file descriptor.

The file descriptor is normally used in subsequent calls to *ftruncate*(2) (for a newly created object) and *mmap*(2). After a call to *mmap*(2) the file descriptor may be closed without affecting the memory mapping.

The operation of **shm_unlink**() is analogous to *unlink*(2): it removes a shared memory object name, and, once all processes have unmapped the object, deallocates and destroys the contents of the associated memory region. After a successful **shm_unlink**(), attempts to **shm_open**() an object with the

same *name* fail (unless **O_CREAT** was specified, in which case a new, distinct object is created).

RETURN VALUE

On success, **shm_open**() returns a file descriptor (a nonnegative integer). On success, **shm_unlink**() returns 0. On failure, both functions return −1 and set *errno* to indicate the error.

ERRORS

EACCES
Permission to **shm_unlink**() the shared memory object was denied.

EACCES
Permission was denied to **shm_open**() *name* in the specified *mode*, or **O_TRUNC** was specified and the caller does not have write permission on the object.

EEXIST
Both **O_CREAT** and **O_EXCL** were specified to **shm_open**() and the shared memory object specified by *name* already exists.

EINVAL
The *name* argument to **shm_open**() was invalid.

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENAMETOOLONG
The length of *name* exceeds **PATH_MAX**.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOENT
An attempt was made to **shm_open**() a *name* that did not exist, and **O_CREAT** was not specified.

ENOENT
An attempt was to made to **shm_unlink**() a *name* that does not exist.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
shm_open(), **shm_unlink**()	Thread safety	MT-Safe locale

VERSIONS

POSIX leaves the behavior of the combination of **O_RDONLY** and **O_TRUNC** unspecified. On Linux, this will successfully truncate an existing shared memory object—this may not be so on other UNIX systems.

The POSIX shared memory object implementation on Linux makes use of a dedicated *tmpfs*(5) filesystem that is normally mounted under */dev/shm*.

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2. POSIX.1-2001.

POSIX.1-2001 says that the group ownership of a newly created shared memory object is set to either the calling process's effective group ID or "a system default group ID". POSIX.1-2008 says that the group ownership may be set to either the calling process's effective group ID or, if the object is visible in the filesystem, the group ID of the parent directory.

EXAMPLES

The programs below employ POSIX shared memory and POSIX unnamed semaphores to exchange a piece of data. The "bounce" program (which must be run first) raises the case of a string that is placed into the shared memory by the "send" program. Once the data has been modified, the "send" program then prints the contents of the modified shared memory. An example execution of the two programs is the following:

```
$ ./pshm_ucase_bounce /myshm &
```

```
[1] 270171
$ ./pshm_ucase_send /myshm hello
HELLO
```

Further detail about these programs is provided below.

Program source: pshm_ucase.h

The following header file is included by both programs below. Its primary purpose is to define a structure that will be imposed on the memory object that is shared between the two programs.

```
#include <fcntl.h>
#include <semaphore.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/mman.h>
#include <sys/stat.h>
#include <unistd.h>

#define errExit(msg)    do { perror(msg); exit(EXIT_FAILURE); \
                        } while (0)

#define BUF_SIZE 1024   /* Maximum size for exchanged string */

/* Define a structure that will be imposed on the shared
   memory object */

struct shmbuf {
    sem_t  sem1;            /* POSIX unnamed semaphore */
    sem_t  sem2;            /* POSIX unnamed semaphore */
    size_t cnt;             /* Number of bytes used in 'buf' */
    char   buf[BUF_SIZE];   /* Data being transferred */
};
```

Program source: pshm_ucase_bounce.c

The "bounce" program creates a new shared memory object with the name given in its command-line argument and sizes the object to match the size of the *shmbuf* structure defined in the header file. It then maps the object into the process's address space, and initializes two POSIX semaphores inside the object to 0.

After the "send" program has posted the first of the semaphores, the "bounce" program upper cases the data that has been placed in the memory by the "send" program and then posts the second semaphore to tell the "send" program that it may now access the shared memory.

```
/* pshm_ucase_bounce.c

   Licensed under GNU General Public License v2 or later.
*/
#include <ctype.h>

#include "pshm_ucase.h"

int
main(int argc, char *argv[])
{
    int            fd;
    char           *shmpath;
    struct shmbuf  *shmp;

    if (argc != 2) {
        fprintf(stderr, "Usage: %s /shm-path\n", argv[0]);
        exit(EXIT_FAILURE);
    }
```

```
        shmpath = argv[1];

        /* Create shared memory object and set its size to the size
           of our structure. */

        fd = shm_open(shmpath, O_CREAT | O_EXCL | O_RDWR, 0600);
        if (fd == -1)
            errExit("shm_open");

        if (ftruncate(fd, sizeof(struct shmbuf)) == -1)
            errExit("ftruncate");

        /* Map the object into the caller's address space. */

        shmp = mmap(NULL, sizeof(*shmp), PROT_READ | PROT_WRITE,
                    MAP_SHARED, fd, 0);
        if (shmp == MAP_FAILED)
            errExit("mmap");

        /* Initialize semaphores as process-shared, with value 0. */

        if (sem_init(&shmp->sem1, 1, 0) == -1)
            errExit("sem_init-sem1");
        if (sem_init(&shmp->sem2, 1, 0) == -1)
            errExit("sem_init-sem2");

        /* Wait for 'sem1' to be posted by peer before touching
           shared memory. */

        if (sem_wait(&shmp->sem1) == -1)
            errExit("sem_wait");

        /* Convert data in shared memory into upper case. */

        for (size_t j = 0; j < shmp->cnt; j++)
            shmp->buf[j] = toupper((unsigned char) shmp->buf[j]);

        /* Post 'sem2' to tell the peer that it can now
           access the modified data in shared memory. */

        if (sem_post(&shmp->sem2) == -1)
            errExit("sem_post");

        /* Unlink the shared memory object. Even if the peer process
           is still using the object, this is okay. The object will
           be removed only after all open references are closed. */

        shm_unlink(shmpath);

        exit(EXIT_SUCCESS);
    }
```

Program source: pshm_ucase_send.c

The "send" program takes two command-line arguments: the pathname of a shared memory object previously created by the "bounce" program and a string that is to be copied into that object.

The program opens the shared memory object and maps the object into its address space. It then copies the data specified in its second argument into the shared memory, and posts the first semaphore, which tells the "bounce" program that it can now access that data. After the "bounce" program posts the

second semaphore, the "send" program prints the contents of the shared memory on standard output.

```

NAME

siginterrupt − allow signals to interrupt system calls

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <signal.h>

[[deprecated]] int siginterrupt(int *sig***, int** *flag***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

siginterrupt():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L
|| /* glibc <= 2.19: */ _BSD_SOURCE

DESCRIPTION

The **siginterrupt**() function changes the restart behavior when a system call is interrupted by the signal *sig*. If the *flag* argument is false (0), then system calls will be restarted if interrupted by the specified signal *sig*. This is the default behavior in Linux.

If the *flag* argument is true (1) and no data has been transferred, then a system call interrupted by the signal *sig* will return −1 and *errno* will be set to **EINTR**.

If the *flag* argument is true (1) and data transfer has started, then the system call will be interrupted and will return the actual amount of data transferred.

RETURN VALUE

The **siginterrupt**() function returns 0 on success. It returns −1 if the signal number *sig* is invalid, with *errno* set to indicate the error.

ERRORS

EINVAL
The specified signal number is invalid.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value

NAME

signbit − test sign of a real floating-point number

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <math.h>

int signbit(*x***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

signbit():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

signbit() is a generic macro which can work on all real floating-point types. It returns a nonzero value if the value of *x* has its sign bit set.

This is not the same as *x < 0.0*, because IEEE 754 floating point allows zero to be signed. The comparison *−0.0 < 0.0* is false, but *signbit(−0.0)* will return a nonzero value.

NaNs and infinities have a sign bit.

RETURN VALUE

The **signbit**() macro returns nonzero if the sign of *x* is negative; otherwise it returns zero.

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
signbit()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NAME

sigpause − atomically release blocked signals and wait for interrupt

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <signal.h>

[[deprecated]] int sigpause(int *sigmask***); /* BSD (but see NOTES) */**

[[deprecated]] int sigpause(int *sig***); /* POSIX.1 / SysV / UNIX 95 */**

DESCRIPTION

Don't use this function. Use *sigsuspend*(2) instead.

The function **sigpause**() is designed to wait for some signal. It changes the process's signal mask (set of blocked signals), and then waits for a signal to arrive. Upon arrival of a signal, the original signal mask is restored.

RETURN VALUE

If **sigpause**() returns, it was interrupted by a signal and the return value is −1 with *errno* set to **EINTR**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sigpause()	Thread safety	MT-Safe

VERSIONS

On Linux, this routine is a system call only on the Sparc (sparc64) architecture.

glibc uses the BSD version if the **_BSD_SOURCE** feature test macro is defined and none of **_POSIX_SOURCE**, **_POSIX_C_SOURCE**, **_XOPEN_SOURCE**, **_GNU_SOURCE**, or **_SVID_SOURCE** is defined. Otherwise, the System V version is used, and feature test macros must be defined as follows to obtain the declaration:

- Since glibc 2.26: _XOPEN_SOURCE >= 500
- glibc 2.25 and earlier: _XOPEN_SOURCE

Since glibc 2.19, only the System V version is exposed by <*signal.h*>; applications that formerly used the BSD **sigpause**() should be amended to use *sigsuspend*(2).

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001. Obsoleted in POSIX.1-2008.

The classical BSD version of this function appeared in 4.2BSD. It sets the process's signal mask to *sigmask*. UNIX 95 standardized the incompatible System V version of this function, which removes only the specified signal *sig* from the process's signal mask. The unfortunate situation with two incompatible functions with the same name was solved by the **sigsuspend**(2) function, that takes a *sigset_t* * argument (instead of an *int*).

SEE ALSO

NAME

sigqueue − queue a signal and data to a process

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>

int sigqueue(pid_t pid, int sig, const union sigval value);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sigqueue():
_POSIX_C_SOURCE >= 199309L

DESCRIPTION

sigqueue() sends the signal specified in *sig* to the process whose PID is given in *pid*. The permissions required to send a signal are the same as for *kill*(2). As with *kill*(2), the null signal (0) can be used to check if a process with a given PID exists.

The *value* argument is used to specify an accompanying item of data (either an integer or a pointer value) to be sent with the signal, and has the following type:

```
union sigval {
    int   sival_int;
    void *sival_ptr;
};
```

If the receiving process has installed a handler for this signal using the **SA_SIGINFO** flag to *sigaction*(2), then it can obtain this data via the *si_value* field of the *siginfo_t* structure passed as the second argument to the handler. Furthermore, the *si_code* field of that structure will be set to **SI_QUEUE**.

RETURN VALUE

On success, **sigqueue**() returns 0, indicating that the signal was successfully queued to the receiving process. Otherwise, −1 is returned and *errno* is set to indicate the error.

ERRORS

EAGAIN
The limit of signals which may be queued has been reached. (See *signal*(7) for further information.)

EINVAL
sig was invalid.

EPERM
The process does not have permission to send the signal to the receiving process. For the required permissions, see *kill*(2).

ESRCH
No process has a PID matching *pid*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sigqueue()	Thread safety	MT-Safe

VERSIONS

C library/kernel differences

On Linux, **sigqueue**() is implemented using the *rt_sigqueueinfo*(2) system call. The system call differs in its third argument, which is the *siginfo_t* structure that will be supplied to the receiving process's signal handler or returned by the receiving process's *sigtimedwait*(2) call. Inside the glibc **sigqueue**() wrapper, this argument, *uinfo*, is initialized as follows:

```
uinfo.si_signo = sig;      /* Argument supplied to sigqueue() */
uinfo.si_code = SI_QUEUE;
uinfo.si_pid = getpid();   /* Process ID of sender */
uinfo.si_uid = getuid();   /* Real UID of sender */
uinfo.si_value = val;      /* Argument supplied to sigqueue() */
```

STANDARDS

POSIX.1-2008.

HISTORY

Linux 2.2. POSIX.1-2001.

NOTES

If this function results in the sending of a signal to the process that invoked it, and that signal was not blocked by the calling thread, and no other threads were willing to handle this signal (either by having it unblocked, or by waiting for it using *sigwait*(3)), then at least some signal must be delivered to this thread before this function returns.

NAME

sigset, sighold, sigrelse, sigignore − System V signal API

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>

typedef void (*sighandler_t)(int);

[[deprecated]] sighandler_t sigset(int sig, sighandler_t disp);

[[deprecated]] int sighold(int sig);
[[deprecated]] int sigrelse(int sig);
[[deprecated]] int sigignore(int sig);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sigset(), **sighold**(), **sigrelse**(), **sigignore**():
_XOPEN_SOURCE >= 500

DESCRIPTION

These functions are provided in glibc as a compatibility interface for programs that make use of the historical System V signal API. This API is obsolete: new applications should use the POSIX signal API (**sigaction**(2), *sigprocmask*(2), etc.)

The **sigset**() function modifies the disposition of the signal *sig*. The *disp* argument can be the address of a signal handler function, or one of the following constants:

SIG_DFL
: Reset the disposition of *sig* to the default.

SIG_IGN
: Ignore *sig*.

SIG_HOLD
: Add *sig* to the process's signal mask, but leave the disposition of *sig* unchanged.

If *disp* specifies the address of a signal handler, then *sig* is added to the process's signal mask during execution of the handler.

If *disp* was specified as a value other than **SIG_HOLD**, then *sig* is removed from the process's signal mask.

The dispositions for **SIGKILL** and **SIGSTOP** cannot be changed.

The **sighold**() function adds *sig* to the calling process's signal mask.

The **sigrelse**() function removes *sig* from the calling process's signal mask.

The **sigignore**() function sets the disposition of *sig* to **SIG_IGN**.

RETURN VALUE

On success, **sigset**() returns **SIG_HOLD** if *sig* was blocked before the call, or the signal's previous disposition if it was not blocked before the call. On error, **sigset**() returns −1, with *errno* set to indicate the error. (But see BUGS below.)

The **sighold**(), **sigrelse**(), and **sigignore**() functions return 0 on success; on error, these functions return −1 and set *errno* to indicate the error.

ERRORS

For **sigset**() see the ERRORS under *sigaction*(2) and *sigprocmask*(2).

For **sighold**() and **sigrelse**() see the ERRORS under *sigprocmask*(2).

For **sigignore**(), see the errors under *sigaction*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sigset(), **sighold**(), **sigrelse**(), **sigignore**()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

sighandler_t

GNU. POSIX.1 uses the same type but without a *typedef*.

HISTORY

glibc 2.1. SVr4, POSIX.1-2001. POSIX.1-2008 marks these functions as obsolete, recommending the use of *sigaction*(2), *sigprocmask*(2), *pthread_sigmask*(3), and *sigsuspend*(2) instead.

NOTES

The **sigset**() function provides reliable signal handling semantics (as when calling *sigaction*(2) with *sa_mask* equal to 0).

On System V, the **signal**() function provides unreliable semantics (as when calling *sigaction*(2) with *sa_mask* equal to *SA_RESETHAND* | *SA_NODEFER*). On BSD, **signal**() provides reliable semantics. POSIX.1-2001 leaves these aspects of **signal**() unspecified. See *signal*(2) for further details.

In order to wait for a signal, BSD and System V both provided a function named *sigpause*(3), but this function has a different argument on the two systems. See *sigpause*(3) for details.

BUGS

Before glibc 2.2, **sigset**() did not unblock *sig* if *disp* was specified as a value other than **SIG_HOLD**.

Before glibc 2.5, **sigset**() does not correctly return the previous disposition of the signal in two cases. First, if *disp* is specified as **SIG_HOLD**, then a successful **sigset**() always returns **SIG_HOLD**. Instead, it should return the previous disposition of the signal (unless the signal was blocked, in which case **SIG_HOLD** should be returned). Second, if the signal is currently blocked, then the return value of a successful **sigset**() should be **SIG_HOLD**. Instead, the previous disposition of the signal is returned. These problems have been fixed since glibc 2.5.

NAME

sigemptyset, sigfillset, sigaddset, sigdelset, sigismember − POSIX signal set operations

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>

int sigemptyset(sigset_t *set);
int sigfillset(sigset_t *set);

int sigaddset(sigset_t *set, int signum);
int sigdelset(sigset_t *set, int signum);

int sigismember(const sigset_t *set, int signum);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sigemptyset(), **sigfillset**(), **sigaddset**(), **sigdelset**(), **sigismember**():
_POSIX_C_SOURCE

DESCRIPTION

These functions allow the manipulation of POSIX signal sets.

sigemptyset() initializes the signal set given by *set* to empty, with all signals excluded from the set.

sigfillset() initializes *set* to full, including all signals.

sigaddset() and **sigdelset**() add and delete respectively signal *signum* from *set*.

sigismember() tests whether *signum* is a member of *set*.

Objects of type *sigset_t* must be initialized by a call to either **sigemptyset**() or **sigfillset**() before being passed to the functions **sigaddset**(), **sigdelset**(), and **sigismember**() or the additional glibc functions described below (**sigisemptyset**(), **sigandset**(), and *sigorset*())The results are undefined if this is not done.

RETURN VALUE

sigemptyset(), **sigfillset**(), **sigaddset**(), and **sigdelset**() return 0 on success and −1 on error.

sigismember() returns 1 if *signum* is a member of *set*, 0 if *signum* is not a member, and −1 on error.

On error, these functions set *errno* to indicate the error.

ERRORS

EINVAL
signum is not a valid signal.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sigemptyset(), **sigfillset**(), **sigaddset**(), **sigdelset**(), **sigismember**(), **sigisemptyset**(), **sigorset**(), **sigandset**()	Thread safety	MT-Safe

VERSIONS

GNU

If the **_GNU_SOURCE** feature test macro is defined, then <*signal.h*> exposes three other functions for manipulating signal sets:

```
int sigisemptyset(const sigset_t *set);
int sigorset(sigset_t *dest, const sigset_t *left,
        const sigset_t *right);
int sigandset(sigset_t *dest, const sigset_t *left,
        const sigset_t *right);
```

sigisemptyset() returns 1 if *set* contains no signals, and 0 otherwise.

sigorset() places the union of the sets *left* and *right* in *dest*. **sigandset**() places the intersection of the sets *left* and *right* in *dest*. Both functions return 0 on success, and −1 on failure.

These functions are nonstandard (a few other systems provide similar functions) and their use should

be avoided in portable applications.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

NOTES

When creating a filled signal set, the glibc **sigfillset**() function does not include the two real-time signals used internally by the NPTL threading implementation. See *nptl*(7) for details.

sigaction(2), *sigpending*(2), *sigprocmask*(2), *sigsuspend*(2)

NAME

sigvec, sigblock, sigsetmask, siggetmask, sigmask − BSD signal API

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <signal.h>

[[deprecated]] int sigvec(int sig, const struct sigvec *vec,
                          struct sigvec *ovec);

[[deprecated]] int sigmask(int signum);

[[deprecated]] int sigblock(int mask);
[[deprecated]] int sigsetmask(int mask);
[[deprecated]] int siggetmask(void);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

These functions are provided in glibc as a compatibility interface for programs that make use of the historical BSD signal API. This API is obsolete: new applications should use the POSIX signal API (**sigaction**(2), *sigprocmask*(2), etc.).

The **sigvec**() function sets and/or gets the disposition of the signal *sig* (like the POSIX *sigaction*(2)). If *vec* is not NULL, it points to a *sigvec* structure that defines the new disposition for *sig*. If *ovec* is not NULL, it points to a *sigvec* structure that is used to return the previous disposition of *sig*. To obtain the current disposition of *sig* without changing it, specify NULL for *vec*, and a non-null pointer for *ovec*.

The dispositions for **SIGKILL** and **SIGSTOP** cannot be changed.

The *sigvec* structure has the following form:

```
struct sigvec {
    void (*sv_handler)(int); /* Signal disposition */
    int    sv_mask;          /* Signals to be blocked in handler */
    int    sv_flags;         /* Flags */
};
```

The *sv_handler* field specifies the disposition of the signal, and is either: the address of a signal handler function; **SIG_DFL**, meaning the default disposition applies for the signal; or **SIG_IGN**, meaning that the signal is ignored.

If *sv_handler* specifies the address of a signal handler, then *sv_mask* specifies a mask of signals that are to be blocked while the handler is executing. In addition, the signal for which the handler is invoked is also blocked. Attempts to block **SIGKILL** or **SIGSTOP** are silently ignored.

If *sv_handler* specifies the address of a signal handler, then the *sv_flags* field specifies flags controlling what happens when the handler is called. This field may contain zero or more of the following flags:

SV_INTERRUPT
: If the signal handler interrupts a blocking system call, then upon return from the handler the system call is not restarted: instead it fails with the error **EINTR**. If this flag is not specified, then system calls are restarted by default.

SV_RESETHAND
: Reset the disposition of the signal to the default before calling the signal handler. If this flag is not specified, then the handler remains established until explicitly removed by a later call to **sigvec**() or until the process performs an *execve*(2).

SV_ONSTACK
Handle the signal on the alternate signal stack (historically established under BSD using the obsolete **sigstack**() function; the POSIX replacement is *sigaltstack*(2)).

The **sigmask**() macro constructs and returns a "signal mask" for *signum*. For example, we can initialize the *vec.sv_mask* field given to **sigvec**() using code such as the following:

```
vec.sv_mask = sigmask(SIGQUIT) | sigmask(SIGABRT);
            /* Block SIGQUIT and SIGABRT during
               handler execution */
```

The **sigblock**() function adds the signals in *mask* to the process's signal mask (like POSIX *sigprocmask(SIG_BLOCK)*), and returns the process's previous signal mask. Attempts to block **SIGKILL** or **SIGSTOP** are silently ignored.

The **sigsetmask**() function sets the process's signal mask to the value given in *mask* (like POSIX *sigprocmask(SIG_SETMASK)*), and returns the process's previous signal mask.

The **siggetmask**() function returns the process's current signal mask. This call is equivalent to *sigblock(0)*.

RETURN VALUE

The **sigvec**() function returns 0 on success; on error, it returns −1 and sets *errno* to indicate the error.

The **sigblock**() and **sigsetmask**() functions return the previous signal mask.

The **sigmask**() macro returns the signal mask for *signum*.

ERRORS

See the ERRORS under *sigaction*(2) and *sigprocmask*(2).

siggetmask()
Unclear origin.

sigvec()
Removed in glibc 2.21.

NOTES

On 4.3BSD, the **signal**() function provided reliable semantics (as when calling **sigvec**() with *vec.sv_mask* equal to 0). On System V, **signal**() provides unreliable semantics. POSIX.1 leaves these aspects of **signal**() unspecified. See *signal*(2) for further details.

In order to wait for a signal, BSD and System V both provided a function named *sigpause*(3), but this function has a different argument on the two systems. See *sigpause*(3) for details.

SEE ALSO

kill(2), *pause*(2), *sigaction*(2), *signal*(2), *sigprocmask*(2), *raise*(3), *sigpause*(3), *sigset*(3), *signal*(7)

NAME

sigwait − wait for a signal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <signal.h>

int sigwait(const sigset_t *restrict *set***, int *restrict** *sig***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sigwait():
Since glibc 2.26:
_POSIX_C_SOURCE >= 199506L
glibc 2.25 and earlier:
_POSIX_C_SOURCE

DESCRIPTION

The **sigwait**() function suspends execution of the calling thread until one of the signals specified in the signal set *set* becomes pending. The function accepts the signal (removes it from the pending list of signals), and returns the signal number in *sig*.

The operation of **sigwait**() is the same as *sigwaitinfo*(2), except that:

- **sigwait**() returns only the signal number, rather than a *siginfo_t* structure describing the signal.
- The return values of the two functions are different.

RETURN VALUE

On success, **sigwait**() returns 0. On error, it returns a positive error number (listed in ERRORS).

ERRORS

EINVAL
set contains an invalid signal number.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sigwait()	Thread safety	MT-Safe

VERSIONS

sigwait() is implemented using *sigtimedwait*(2).

The glibc implementation of **sigwait**() silently ignores attempts to wait for the two real-time signals that are used internally by the NPTL threading implementation. See *nptl*(7) for details.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

See *pthread_sigmask*(3).

SEE ALSO

sigaction(2), *signalfd*(2), *sigpending*(2), *sigsuspend*(2), *sigwaitinfo*(2), *sigsetops*(3), *signal*(7)

NAME

sin, sinf, sinl − sine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double sin(double x);
float sinf(float x);
long double sinl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sinf(), **sinl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the sine of *x*, where *x* is given in radians.

RETURN VALUE

On success, these functions return the sine of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity or negative infinity, a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sin(), **sinf**(), **sinl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

BUGS

Before glibc 2.10, the glibc implementation did not set *errno* to **EDOM** when a domain error occurred.

SEE ALSO

acos(3), *asin*(3), *atan*(3), *atan2*(3), *cos*(3), *csin*(3), *sincos*(3), *tan*(3)

NAME

sincos, sincosf, sincosl − calculate sin and cos simultaneously

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <math.h>

void sincos(double x, double *sin, double *cos);
void sincosf(float x, float *sin, float *cos);
void sincosl(long double x, long double *sin, long double *cos);
```

DESCRIPTION

Several applications need sine and cosine of the same angle *x*. These functions compute both at the same time, and store the results in **sin* and **cos*. Using this function can be more efficient than two separate calls to *sin*(3) and *cos*(3).

If *x* is a NaN, a NaN is returned in **sin* and **cos*.

If *x* is positive infinity or negative infinity, a domain error occurs, and a NaN is returned in **sin* and **cos*.

RETURN VALUE

These functions return *void*.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sincos(), **sincosf**(), **sincosl**()	Thread safety	MT-Safe

STANDARDS

GNU.

HISTORY

glibc 2.1.

NOTES

To see the performance advantage of **sincos**(), it may be necessary to disable *gcc*(1) built-in optimizations, using flags such as:

```
cc -O -lm -fno-builtin prog.c
```

BUGS

Before glibc 2.22, the glibc implementation did not set *errno* to **EDOM** when a domain error occurred.

SEE ALSO

cos(3), *sin*(3), *tan*(3)

NAME

sinh, sinhf, sinhl − hyperbolic sine function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double sinh(double x);
float sinhf(float x);
long double sinhl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sinhf(), **sinhl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the hyperbolic sine of *x*, which is defined mathematically as:

sinh(x) = (exp(x) − exp(−x)) / 2

RETURN VALUE

On success, these functions return the hyperbolic sine of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is positive infinity (negative infinity), positive infinity (negative infinity) is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the same sign as *x*.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Range error: result overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sinh(), **sinhf**(), **sinhl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

NAME

sleep − sleep for a specified number of seconds

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

unsigned int sleep(unsigned int *seconds***);**

DESCRIPTION

sleep() causes the calling thread to sleep either until the number of real-time seconds specified in *seconds* have elapsed or until a signal arrives which is not ignored.

RETURN VALUE

Zero if the requested time has elapsed, or the number of seconds left to sleep, if the call was interrupted by a signal handler.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sleep()	Thread safety	MT-Unsafe sig:SIGCHLD/linux

VERSIONS

On Linux, **sleep**() is implemented via *nanosleep*(2). See the *nanosleep*(2) man page for a discussion of the clock used.

On some systems, **sleep**() may be implemented using *alarm*(2) and **SIGALRM** (POSIX.1 permits this); mixing calls to *alarm*(2) and **sleep**() is a bad idea.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

CAVEATS

Using *longjmp*(3) from a signal handler or modifying the handling of **SIGALRM** while sleeping will cause undefined results.

SEE ALSO

sleep(1), *alarm*(2), *nanosleep*(2), *signal*(2), *signal*(7)

NAME

SLIST_EMPTY, SLIST_ENTRY, SLIST_FIRST, SLIST_FOREACH, SLIST_HEAD, SLIST_HEAD_INITIALIZER, SLIST_INIT, SLIST_INSERT_AFTER, SLIST_INSERT_HEAD, SLIST_NEXT, SLIST_REMOVE, SLIST_REMOVE_HEAD − implementation of a singly linked list

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/queue.h>

SLIST_ENTRY(TYPE);

SLIST_HEAD(HEADNAME, TYPE);
SLIST_HEAD SLIST_HEAD_INITIALIZER(SLIST_HEAD *head***);**
void SLIST_INIT(SLIST_HEAD ***_head_);**

int SLIST_EMPTY(SLIST_HEAD ***_head_);**

void SLIST_INSERT_HEAD(SLIST_HEAD ***_head_,**
struct TYPE ***_elm_, SLIST_ENTRY** *NAME***);**
void SLIST_INSERT_AFTER(struct TYPE ***_listelm_,**
struct TYPE ***_elm_, SLIST_ENTRY** *NAME***);**

struct TYPE *SLIST_FIRST(SLIST_HEAD ***_head_);**
struct TYPE *SLIST_NEXT(struct TYPE ***_elm_, SLIST_ENTRY** *NAME***);**

SLIST_FOREACH(struct TYPE ***_var_, SLIST_HEAD ***_head_**, SLIST_ENTRY** *NAME***);**

void SLIST_REMOVE(SLIST_HEAD ***_head_, struct TYPE ***_elm_**,**
SLIST_ENTRY *NAME***);**
void SLIST_REMOVE_HEAD(SLIST_HEAD ***_head_,**
SLIST_ENTRY *NAME***);**

DESCRIPTION

These macros define and operate on doubly linked lists.

In the macro definitions, *TYPE* is the name of a user-defined structure, that must contain a field of type *SLIST_ENTRY*, named *NAME*. The argument *HEADNAME* is the name of a user-defined structure that must be declared using the macro **SLIST_HEAD**().

Creation

A singly linked list is headed by a structure defined by the **SLIST_HEAD**() macro. This structure contains a single pointer to the first element on the list. The elements are singly linked for minimum space and pointer manipulation overhead at the expense of O(n) removal for arbitrary elements. New elements can be added to the list after an existing element or at the head of the list. An *SLIST_HEAD* structure is declared as follows:

```
SLIST_HEAD(HEADNAME, TYPE) head;
```

where *struct HEADNAME* is the structure to be defined, and *struct TYPE* is the type of the elements to be linked into the list. A pointer to the head of the list can later be declared as:

```
struct HEADNAME *headp;
```

(The names *head* and *headp* are user selectable.)

SLIST_ENTRY() declares a structure that connects the elements in the list.

SLIST_HEAD_INITIALIZER() evaluates to an initializer for the list *head*.

SLIST_INIT() initializes the list referenced by *head*.

SLIST_EMPTY() evaluates to true if there are no elements in the list.

Insertion

SLIST_INSERT_HEAD() inserts the new element *elm* at the head of the list.

SLIST_INSERT_AFTER() inserts the new element *elm* after the element *listelm*.

Traversal

SLIST_FIRST() returns the first element in the list, or NULL if the list is empty.

SLIST_NEXT() returns the next element in the list.

SLIST_FOREACH() traverses the list referenced by *head* in the forward direction, assigning each element in turn to *var*.

Removal

SLIST_REMOVE() removes the element *elm* from the list.

SLIST_REMOVE_HEAD() removes the element *elm* from the head of the list. For optimum efficiency, elements being removed from the head of the list should explicitly use this macro instead of the generic **SLIST_REMOVE**().

RETURN VALUE

SLIST_EMPTY() returns nonzero if the list is empty, and zero if the list contains at least one entry.

SLIST_FIRST(), and **SLIST_NEXT**() return a pointer to the first or next *TYPE* structure, respectively.

SLIST_HEAD_INITIALIZER() returns an initializer that can be assigned to the list *head*.

STANDARDS

BSD.

HISTORY

4.4BSD.

BUGS

SLIST_FOREACH() doesn't allow *var* to be removed or freed within the loop, as it would interfere with the traversal. **SLIST_FOREACH_SAFE**(), which is present on the BSDs but is not present in glibc, fixes this limitation by allowing *var* to safely be removed from the list and freed from within the loop without interfering with the traversal.

EXAMPLES

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/queue.h>

struct entry {
    int data;
    SLIST_ENTRY(entry) entries;             /* Singly linked list */
};

SLIST_HEAD(slisthead, entry);

int
main(void)
{
    struct entry *n1, *n2, *n3, *np;
    struct slisthead head;                  /* Singly linked list
                                               head */

    SLIST_INIT(&head);                      /* Initialize the queue */

    n1 = malloc(sizeof(struct entry));      /* Insert at the head */
    SLIST_INSERT_HEAD(&head, n1, entries);

    n2 = malloc(sizeof(struct entry));      /* Insert after */
    SLIST_INSERT_AFTER(n1, n2, entries);

    SLIST_REMOVE(&head, n2, entry, entries);/* Deletion */
    free(n2);
```

```
        n3 = SLIST_FIRST(&head);
        SLIST_REMOVE_HEAD(&head, entries);      /* Deletion from the head */
        free(n3);

        for (unsigned int i = 0; i < 5; i++) {
            n1 = malloc(sizeof(struct entry));
            SLIST_INSERT_HEAD(&head, n1, entries);
            n1->data = i;
        }

                                                /* Forward traversal */
        SLIST_FOREACH(np, &head, entries)
            printf("%i\n", np->data);

        while (!SLIST_EMPTY(&head)) {           /* List deletion */
            n1 = SLIST_FIRST(&head);
            SLIST_REMOVE_HEAD(&head, entries);
            free(n1);
        }
        SLIST_INIT(&head);

        exit(EXIT_SUCCESS);
    }
```

SEE ALSO

insque(3), *queue*(7)

NAME

sockatmark − determine whether socket is at out-of-band mark

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/socket.h>

int sockatmark(int *sockfd***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sockatmark():
_POSIX_C_SOURCE >= 200112L

DESCRIPTION

sockatmark() returns a value indicating whether or not the socket referred to by the file descriptor *sockfd* is at the out-of-band mark. If the socket is at the mark, then 1 is returned; if the socket is not at the mark, 0 is returned. This function does not remove the out-of-band mark.

RETURN VALUE

A successful call to **sockatmark**() returns 1 if the socket is at the out-of-band mark, or 0 if it is not. On error, −1 is returned and *errno* is set to indicate the error.

ERRORS

EBADF
sockfd is not a valid file descriptor.

EINVAL
sockfd is not a file descriptor to which **sockatmark**() can be applied.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sockatmark()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

glibc 2.2.4. POSIX.1-2001.

NOTES

If **sockatmark**() returns 1, then the out-of-band data can be read using the **MSG_OOB** flag of *recv*(2).

Out-of-band data is supported only on some stream socket protocols.

sockatmark() can safely be called from a handler for the **SIGURG** signal.

sockatmark() is implemented using the **SIOCATMARK** *ioctl*(2) operation.

BUGS

Prior to glibc 2.4, **sockatmark**() did not work.

EXAMPLES

The following code can be used after receipt of a **SIGURG** signal to read (and discard) all data up to the mark, and then read the byte of data at the mark:

```
char buf[BUF_LEN];
char oobdata;
int atmark, s;

for (;;) {
    atmark = sockatmark(sockfd);
    if (atmark == -1) {
        perror("sockatmark");
        break;
    }
```

```
            if (atmark)
                break;

            s = read(sockfd, buf, BUF_LEN);
            if (s == -1)
                perror("read");
            if (s <= 0)
                break;
        }

        if (atmark == 1) {
            if (recv(sockfd, &oobdata, 1, MSG_OOB) == -1) {
                perror("recv");
                ...
            }
        }
```

SEE ALSO

fcntl(2), *recv*(2), *send*(2), *tcp*(7)

NAME

sqrt, sqrtf, sqrtl − square root function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double sqrt(double x);
float sqrtf(float x);
long double sqrtl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sqrtf(), **sqrtl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the nonnegative square root of *x*.

RETURN VALUE

On success, these functions return the square root of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is positive infinity, positive infinity is returned.

If *x* is less than −0, a domain error occurs, and a NaN is returned.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* less than −0
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sqrt(), **sqrtf**(), **sqrtl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

SEE ALSO

NAME

sscanf, vsscanf − input string format conversion

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

int sscanf(const char *restrict str,
           const char *restrict format, ...);

#include <stdarg.h>

int vsscanf(const char *restrict str,
           const char *restrict format, va_list ap);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

vsscanf():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **sscanf**() family of functions scans formatted input according to *format* as described below. This format may contain *conversion specifications*; the results from such conversions, if any, are stored in the locations pointed to by the *pointer* arguments that follow *format*. Each *pointer* argument must be of a type that is appropriate for the value returned by the corresponding conversion specification.

If the number of conversion specifications in *format* exceeds the number of *pointer* arguments, the results are undefined. If the number of *pointer* arguments exceeds the number of conversion specifications, then the excess *pointer* arguments are evaluated, but are otherwise ignored.

sscanf() These functions read their input from the string pointed to by *str*.

The **vsscanf**() function is analogous to *vsprintf*(3).

The *format* string consists of a sequence of *directives* which describe how to process the sequence of input characters. If processing of a directive fails, no further input is read, and **sscanf**() returns. A "failure" can be either of the following: *input failure*, meaning that input characters were unavailable, or *matching failure*, meaning that the input was inappropriate (see below).

A directive is one of the following:

- A sequence of white-space characters (space, tab, newline, etc.; see *isspace*(3)). This directive matches any amount of white space, including none, in the input.
- An ordinary character (i.e., one other than white space or '%'). This character must exactly match the next character of input.
- A conversion specification, which commences with a '%' (percent) character. A sequence of characters from the input is converted according to this specification, and the result is placed in the corresponding *pointer* argument. If the next item of input does not match the conversion specification, the conversion fails—this is a *matching failure*.

Each *conversion specification* in *format* begins with either the character '%' or the character sequence "**%***n***$**" (see below for the distinction) followed by:

- An optional '*' assignment-suppression character: **sscanf**() reads input as directed by the conversion specification, but discards the input. No corresponding *pointer* argument is required, and this specification is not included in the count of successful assignments returned by **scanf**().
- For decimal conversions, an optional quote character ('). This specifies that the input number may include thousands' separators as defined by the **LC_NUMERIC** category of the current locale. (See *setlocale*(3).) The quote character may precede or follow the '*' assignment-suppression character.
- An optional 'm' character. This is used with string conversions (*%s*, *%c*, *%[*), and relieves the caller of the need to allocate a corresponding buffer to hold the input: instead, **sscanf**() allocates a buffer of sufficient size, and assigns the address of this buffer to the corresponding *pointer* argument, which should be a pointer to a *char* * variable (this variable does not need

to be initialized before the call). The caller should subsequently *free*(3) this buffer when it is no longer required.

- An optional decimal integer which specifies the *maximum field width*. Reading of characters stops either when this maximum is reached or when a nonmatching character is found, whichever happens first. Most conversions discard initial white space characters (the exceptions are noted below), and these discarded characters don't count toward the maximum field width. String input conversions store a terminating null byte ('\0') to mark the end of the input; the maximum field width does not include this terminator.
- An optional *type modifier character*. For example, the **l** type modifier is used with integer conversions such as **%d** to specify that the corresponding *pointer* argument refers to a *long* rather than a pointer to an *int*.
- A *conversion specifier* that specifies the type of input conversion to be performed.

The conversion specifications in *format* are of two forms, either beginning with '%' or beginning with "**%***n***$**". The two forms should not be mixed in the same *format* string, except that a string containing "**%***n***$**" specifications can include **%%** and **%***. If *format* contains '%' specifications, then these correspond in order with successive *pointer* arguments. In the "**%***n***$**" form (which is specified in POSIX.1-2001, but not C99), *n* is a decimal integer that specifies that the converted input should be placed in the location referred to by the *n*-th *pointer* argument following *format*.

Conversions

The following *type modifier characters* can appear in a conversion specification:

h Indicates that the conversion will be one of **d**, **i**, **o**, **u**, **x**, **X**, or **n** and the next pointer is a pointer to a *short* or *unsigned short* (rather than *int*).

hh As for **h**, but the next pointer is a pointer to a *signed char* or *unsigned char*.

j As for **h**, but the next pointer is a pointer to an *intmax_t* or a *uintmax_t*. This modifier was introduced in C99.

l Indicates either that the conversion will be one of **d**, **i**, **o**, **u**, **x**, **X**, or **n** and the next pointer is a pointer to a *long* or *unsigned long* (rather than *int*), or that the conversion will be one of **e**, **f**, or **g** and the next pointer is a pointer to *double* (rather than *float*). If used with **%c** or **%s**, the corresponding parameter is considered as a pointer to a wide character or wide-character string respectively.

ll (ell-ell) Indicates that the conversion will be one of **b**, **d**, **i**, **o**, **u**, **x**, **X**, or **n** and the next pointer is a pointer to a *long long* or *unsigned long long* (rather than *int*).

L Indicates that the conversion will be either **e**, **f**, or **g** and the next pointer is a pointer to *long double* or (as a GNU extension) the conversion will be **d**, **i**, **o**, **u**, or **x** and the next pointer is a pointer to *long long*.

q equivalent to **L**. This specifier does not exist in ANSI C.

t As for **h**, but the next pointer is a pointer to a *ptrdiff_t*. This modifier was introduced in C99.

z As for **h**, but the next pointer is a pointer to a *size_t*. This modifier was introduced in C99.

The following *conversion specifiers* are available:

% Matches a literal '%'. That is, **%%** in the format string matches a single input '%' character. No conversion is done (but initial white space characters are discarded), and assignment does not occur.

d Matches an optionally signed decimal integer; the next pointer must be a pointer to *int*.

i Matches an optionally signed integer; the next pointer must be a pointer to *int*. The integer is read in base 16 if it begins with *0x* or *0X*, in base 8 if it begins with *0*, and in base 10 otherwise. Only characters that correspond to the base are used.

o Matches an unsigned octal integer; the next pointer must be a pointer to *unsigned int*.

u Matches an unsigned decimal integer; the next pointer must be a pointer to *unsigned int*.

x Matches an unsigned hexadecimal integer (that may optionally begin with a prefix of *0x* or *0X*, which is discarded); the next pointer must be a pointer to *unsigned int*.

X Equivalent to **x**.

f Matches an optionally signed floating-point number; the next pointer must be a pointer to *float*.

e Equivalent to **f**.

g Equivalent to **f**.

E Equivalent to **f**.

a (C99) Equivalent to **f**.

s Matches a sequence of non-white-space characters; the next pointer must be a pointer to the initial element of a character array that is long enough to hold the input sequence and the terminating null byte ('\0'), which is added automatically. The input string stops at white space or at the maximum field width, whichever occurs first.

c Matches a sequence of characters whose length is specified by the *maximum field width* (default 1); the next pointer must be a pointer to *char*, and there must be enough room for all the characters (no terminating null byte is added). The usual skip of leading white space is suppressed. To skip white space first, use an explicit space in the format.

[Matches a nonempty sequence of characters from the specified set of accepted characters; the next pointer must be a pointer to *char*, and there must be enough room for all the characters in the string, plus a terminating null byte. The usual skip of leading white space is suppressed. The string is to be made up of characters in (or not in) a particular set; the set is defined by the characters between the open bracket **[** character and a close bracket **]** character. The set *excludes* those characters if the first character after the open bracket is a circumflex (^). To include a close bracket in the set, make it the first character after the open bracket or the circumflex; any other position will end the set. The hyphen character − is also special; when placed between two other characters, it adds all intervening characters to the set. To include a hyphen, make it the last character before the final close bracket. For instance, **[^]0−9−]** means the set "everything except close bracket, zero through nine, and hyphen". The string ends with the appearance of a character not in the (or, with a circumflex, in) set or when the field width runs out.

p Matches a pointer value (as printed by **%p** in *printf*(3)); the next pointer must be a pointer to a pointer to *void*.

n Nothing is expected; instead, the number of characters consumed thus far from the input is stored through the next pointer, which must be a pointer to *int*, or variant whose size matches the (optionally) supplied integer length modifier. This is *not* a conversion and does *not* increase the count returned by the function. The assignment can be suppressed with the ***** assignment-suppression character, but the effect on the return value is undefined. Therefore **%*n** conversions should not be used.

RETURN VALUE

On success, these functions return the number of input items successfully matched and assigned; this can be fewer than provided for, or even zero, in the event of an early matching failure.

The value **EOF** is returned if the end of input is reached before either the first successful conversion or a matching failure occurs.

ERRORS

EILSEQ
Input byte sequence does not form a valid character.

EINVAL
Not enough arguments; or *format* is NULL.

ENOMEM
Out of memory.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sscanf(), **vsscanf**()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

C89, POSIX.1-2001.

The **q** specifier is the 4.4BSD notation for *long long*, while **ll** or the usage of **L** in integer conversions is the GNU notation.

The Linux version of these functions is based on the *GNU libio* library. Take a look at the *info* documentation of *GNU libc (glibc-1.08)* for a more concise description.

NOTES

The 'a' assignment-allocation modifier

Originally, the GNU C library supported dynamic allocation for string inputs (as a nonstandard extension) via the **a** character. (This feature is present at least as far back as glibc 2.0.) Thus, one could write the following to have **sscanf**() allocate a buffer for a string, with a pointer to that buffer being returned in **buf*:

```
char *buf;
sscanf(str, "%as", &buf);
```

The use of the letter **a** for this purpose was problematic, since **a** is also specified by the ISO C standard as a synonym for **f** (floating-point input). POSIX.1-2008 instead specifies the **m** modifier for assignment allocation (as documented in DESCRIPTION, above).

Note that the **a** modifier is not available if the program is compiled with *gcc −std=c99* or *gcc −D_ISOC99_SOURCE* (unless **_GNU_SOURCE** is also specified), in which case the **a** is interpreted as a specifier for floating-point numbers (see above).

Support for the **m** modifier was added to glibc 2.7, and new programs should use that modifier instead of **a**.

As well as being standardized by POSIX, the **m** modifier has the following further advantages over the use of **a**:

- It may also be applied to **%c** conversion specifiers (e.g., **%3mc**).
- It avoids ambiguity with respect to the **%a** floating-point conversion specifier (and is unaffected by *gcc −std=c99* etc.).

BUGS

Numeric conversion specifiers

Use of the numeric conversion specifiers produces Undefined Behavior for invalid input. See C11 7.21.6.2/10. This is a bug in the ISO C standard, and not an inherent design issue with the API. However, current implementations are not safe from that bug, so it is not recommended to use them. Instead, programs should use functions such as *strtol*(3) to parse numeric input. Alternatively, mitigate it by specifying a maximum field width.

Nonstandard modifiers

These functions are fully C99 conformant, but provide the additional modifiers **q** and **a** as well as an additional behavior of the **L** and **ll** modifiers. The latter may be considered to be a bug, as it changes the behavior of modifiers defined in C99.

Some combinations of the type modifiers and conversion specifiers defined by C99 do not make sense (e.g., **%Ld**). While they may have a well-defined behavior on Linux, this need not to be so on other architectures. Therefore it usually is better to use modifiers that are not defined by C99 at all, that is, use **q** instead of **L** in combination with **d**, **i**, **o**, **u**, **x**, and **X** conversions or **ll**.

The usage of **q** is not the same as on 4.4BSD, as it may be used in float conversions equivalently to **L**.

EXAMPLES

To use the dynamic allocation conversion specifier, specify **m** as a length modifier (thus **%ms** or **%m[***range***]**). The caller must *free*(3) the returned string, as in the following example:

```
char *p;
int n;

errno = 0;
n = sscanf(str, "%m[a-z]", &p);
if (n == 1) {
    printf("read: %s\n", p);
    free(p);
} else if (errno != 0) {
    perror("sscanf");
} else {
    fprintf(stderr, "No matching characters\n");
}
```

As shown in the above example, it is necessary to call *free*(3) only if the **sscanf**() call successfully read a string.

void STAILQ_CONCAT(STAILQ_HEAD ***_head1_, STAILQ_HEAD ***_head2_**);**
Note: Identical macros prefixed with SIMPLEQ instead of STAILQ exist; see NOTES.

DESCRIPTION

These macros define and operate on singly linked tail queues.

In the macro definitions, *TYPE* is the name of a user-defined structure, that must contain a field of type *STAILQ_ENTRY*, named *NAME*. The argument *HEADNAME* is the name of a user-defined structure that must be declared using the macro **STAILQ_HEAD**().

Creation

A singly linked tail queue is headed by a structure defined by the **STAILQ_HEAD**() macro. This structure contains a pair of pointers, one to the first element in the tail queue and the other to the last element in the tail queue. The elements are singly linked for minimum space and pointer manipulation overhead at the expense of O(n) removal for arbitrary elements. New elements can be added to the tail queue after an existing element, at the head of the tail queue, or at the end of the tail queue. A *STAILQ_HEAD* structure is declared as follows:

```
STAILQ_HEAD(HEADNAME, TYPE) head;
```

where *struct HEADNAME* is the structure to be defined, and *struct TYPE* is the type of the elements to be linked into the tail queue. A pointer to the head of the tail queue can later be declared as:

```
struct HEADNAME *headp;
```

(The names *head* and *headp* are user selectable.)

STAILQ_ENTRY() declares a structure that connects the elements in the tail queue.

STAILQ_HEAD_INITIALIZER() evaluates to an initializer for the tail queue *head*.

STAILQ_INIT() initializes the tail queue referenced by *head*.

STAILQ_EMPTY() evaluates to true if there are no items on the tail queue.

Insertion

STAILQ_INSERT_HEAD() inserts the new element *elm* at the head of the tail queue.

STAILQ_INSERT_TAIL() inserts the new element *elm* at the end of the tail queue.

STAILQ_INSERT_AFTER() inserts the new element *elm* after the element *listelm*.

Traversal

STAILQ_FIRST() returns the first item on the tail queue or NULL if the tail queue is empty.

STAILQ_NEXT() returns the next item on the tail queue, or NULL this item is the last.

STAILQ_FOREACH() traverses the tail queue referenced by *head* in the forward direction, assigning each element in turn to *var*.

Removal

STAILQ_REMOVE() removes the element *elm* from the tail queue.

STAILQ_REMOVE_HEAD() removes the element at the head of the tail queue. For optimum efficiency, elements being removed from the head of the tail queue should use this macro explicitly rather than the generic **STAILQ_REMOVE**() macro.

Other features

STAILQ_CONCAT() concatenates the tail queue headed by *head2* onto the end of the one headed by *head1* removing all entries from the former.

RETURN VALUE

STAILQ_EMPTY() returns nonzero if the queue is empty, and zero if the queue contains at least one entry.

STAILQ_FIRST(), and **STAILQ_NEXT**() return a pointer to the first or next *TYPE* structure, respectively.

STAILQ_HEAD_INITIALIZER() returns an initializer that can be assigned to the queue *head*.

VERSIONS

Some BSDs provide SIMPLEQ instead of STAILQ. They are identical, but for historical reasons they were named differently on different BSDs. STAILQ originated on FreeBSD, and SIMPLEQ originated on NetBSD. For compatibility reasons, some systems provide both sets of macros. glibc provides both STAILQ and SIMPLEQ, which are identical except for a missing SIMPLEQ equivalent to **STAILQ_CONCAT**().

BUGS

STAILQ_FOREACH() doesn't allow *var* to be removed or freed within the loop, as it would interfere with the traversal. **STAILQ_FOREACH_SAFE**(), which is present on the BSDs but is not present in glibc, fixes this limitation by allowing *var* to safely be removed from the list and freed from within the loop without interfering with the traversal.

STANDARDS

BSD.

HISTORY

4.4BSD.

EXAMPLES

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/queue.h>

struct entry {
    int data;
    STAILQ_ENTRY(entry) entries;        /* Singly linked tail queue */
};
```

```
STAILQ_HEAD(stailhead, entry);

int
main(void)
{
    struct entry *n1, *n2, *n3, *np;
    struct stailhead head;                  /* Singly linked tail queue
                                               head */

    STAILQ_INIT(&head);                     /* Initialize the queue */

    n1 = malloc(sizeof(struct entry));      /* Insert at the head */
    STAILQ_INSERT_HEAD(&head, n1, entries);

    n1 = malloc(sizeof(struct entry));      /* Insert at the tail */
    STAILQ_INSERT_TAIL(&head, n1, entries);

    n2 = malloc(sizeof(struct entry));      /* Insert after */
    STAILQ_INSERT_AFTER(&head, n1, n2, entries);

    STAILQ_REMOVE(&head, n2, entry, entries); /* Deletion */
    free(n2);

    n3 = STAILQ_FIRST(&head);
    STAILQ_REMOVE_HEAD(&head, entries);     /* Deletion from the head */
    free(n3);

    n1 = STAILQ_FIRST(&head);
    n1->data = 0;
    for (unsigned int i = 1; i < 5; i++) {
        n1 = malloc(sizeof(struct entry));
        STAILQ_INSERT_HEAD(&head, n1, entries);
        n1->data = i;
    }
                                            /* Forward traversal */
    STAILQ_FOREACH(np, &head, entries)
        printf("%i\n", np->data);
                                            /* TailQ deletion */
    n1 = STAILQ_FIRST(&head);
    while (n1 != NULL) {
        n2 = STAILQ_NEXT(n1, entries);
        free(n1);
        n1 = n2;
    }
    STAILQ_INIT(&head);

    exit(EXIT_SUCCESS);
}
```

NAME

static_assert, _Static_assert − fail compilation if assertion is false

LIBRARY

Standard C library (*libc*)

SYNOPSIS

#include <assert.h>

void static_assert(scalar *constant-expression***, const char ****msg***);**

/* Since C23: */
void static_assert(scalar *constant-expression***);**

DESCRIPTION

This macro is similar to **assert**(3), but it works at compile time, generating a compilation error (with an optional message) when the input is false (i.e., compares equal to zero).

If the input is nonzero, no code is emitted.

msg must be a string literal. Since C23, this argument is optional.

There's a keyword, **_Static_assert**(), that behaves identically, and can be used without including <*assert.h*>.

RETURN VALUE

No value is returned.

VERSIONS

In C11, the second argument (*msg*) was mandatory; since C23, it can be omitted.

STANDARDS

C11 and later.

EXAMPLES

static_assert() can't be used in some places, like for example at global scope. For that, a macro **must_be**() can be written in terms of **static_assert**(). The following program uses the macro to get the size of an array safely.

```
#include <assert.h>
#include <stddef.h>
#include <stdint.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/*
 * This macro behaves like static_assert(), failing to
 * compile if its argument is not true.  However, it always
 * returns 0, which allows using it everywhere an expression
 * can be used.
 */
#define must_be(e)                                              \
(                                                               \
    0 * (int) sizeof(                                           \
        struct {                                                \
            static_assert(e);                                   \
            int  ISO_C_forbids_a_struct_with_no_members;        \
        }                                                       \
    )                                                           \
)

#define is_same_type(a, b)  \
    __builtin_types_compatible_p(typeof(a), typeof(b))

#define is_array(arr)       (!is_same_type((arr), &*(arr)))
```

```
#define must_be_array(arr)  must_be(is_array(arr))

#define sizeof_array(arr)   (sizeof(arr) + must_be_array(arr))
#define nitems(arr)         (sizeof((arr)) / sizeof((arr)[0]) \
                             + must_be_array(arr))

int     foo[10];
int8_t  bar[sizeof_array(foo)];

int
main(void)
{
    for (size_t i = 0; i < nitems(foo); i++) {
        foo[i] = i;
    }

    memcpy(bar, foo, sizeof_array(bar));

    for (size_t i = 0; i < nitems(bar); i++) {
        printf("%d,", bar[i]);
    }

    exit(EXIT_SUCCESS);
}
```

NAME

statvfs, fstatvfs − get filesystem statistics

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <sys/statvfs.h>

int statvfs(const char *restrict *path***, struct statvfs *restrict** *buf***);**
int fstatvfs(int *fd***, struct statvfs ***buf***);**

DESCRIPTION

The function **statvfs**() returns information about a mounted filesystem. *path* is the pathname of any file within the mounted filesystem. *buf* is a pointer to a *statvfs* structure defined approximately as follows:

```
struct statvfs {
    unsigned long  f_bsize;    /* Filesystem block size */
    unsigned long  f_frsize;   /* Fragment size */
    fsblkcnt_t     f_blocks;   /* Size of fs in f_frsize units */
    fsblkcnt_t     f_bfree;    /* Number of free blocks */
    fsblkcnt_t     f_bavail;   /* Number of free blocks for
                                  unprivileged users */
    fsfilcnt_t     f_files;    /* Number of inodes */
    fsfilcnt_t     f_ffree;    /* Number of free inodes */
    fsfilcnt_t     f_favail;   /* Number of free inodes for
                                  unprivileged users */
    unsigned long  f_fsid;     /* Filesystem ID */
    unsigned long  f_flag;     /* Mount flags */
    unsigned long  f_namemax;  /* Maximum filename length */
};
```

Here the types *fsblkcnt_t* and *fsfilcnt_t* are defined in <*sys/types.h*>. Both used to be *unsigned long*.

The field *f_flag* is a bit mask indicating various options that were employed when mounting this filesystem. It contains zero or more of the following flags:

ST_MANDLOCK
Mandatory locking is permitted on the filesystem (see *fcntl*(2)).

ST_NOATIME
Do not update access times; see *mount*(2).

ST_NODEV
Disallow access to device special files on this filesystem.

ST_NODIRATIME
Do not update directory access times; see *mount*(2).

ST_NOEXEC
Execution of programs is disallowed on this filesystem.

ST_NOSUID
The set-user-ID and set-group-ID bits are ignored by *exec*(3) for executable files on this filesystem

ST_RDONLY
This filesystem is mounted read-only.

ST_RELATIME
Update atime relative to mtime/ctime; see *mount*(2).

ST_SYNCHRONOUS
Writes are synched to the filesystem immediately (see the description of **O_SYNC** in *open*(2)).

It is unspecified whether all members of the returned struct have meaningful values on all filesystems.

fstatvfs() returns the same information about an open file referenced by descriptor *fd*.

RETURN VALUE

On success, zero is returned. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EACCES
(**statvfs**()) Search permission is denied for a component of the path prefix of *path*. (See also *path_resolution*(7).)

EBADF
(**fstatvfs**()) *fd* is not a valid open file descriptor.

EFAULT
Buf or *path* points to an invalid address.

EINTR
This call was interrupted by a signal; see *signal*(7).

EIO An I/O error occurred while reading from the filesystem.

ELOOP
(**statvfs**()) Too many symbolic links were encountered in translating *path*.

ENAMETOOLONG
(**statvfs**()) *path* is too long.

ENOENT
(**statvfs**()) The file referred to by *path* does not exist.

ENOMEM
Insufficient kernel memory was available.

ENOSYS
The filesystem does not support this call.

ENOTDIR
(**statvfs**()) A component of the path prefix of *path* is not a directory.

EOVERFLOW
Some values were too large to be represented in the returned struct.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
statvfs(), **fstatvfs**()	Thread safety	MT-Safe

VERSIONS

Only the **ST_NOSUID** and **ST_RDONLY** flags of the *f_flag* field are specified in POSIX.1. To obtain definitions of the remaining flags, one must define **_GNU_SOURCE**.

NOTES

The Linux kernel has system calls *statfs*(2) and *fstatfs*(2) to support this library call.

The glibc implementations of

```
pathconf(path, _PC_REC_XFER_ALIGN);
pathconf(path, _PC_ALLOC_SIZE_MIN);
pathconf(path, _PC_REC_MIN_XFER_SIZE);
```

respectively use the *f_frsize*, *f_frsize*, and *f_bsize* fields returned by a call to **statvfs**() with the argument *path*.

Under Linux, *f_favail* is always the same as *f_ffree*, and there's no way for a filesystem to report otherwise. This is not an issue, since no filesystems with an inode root reservation exist.

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

Before glibc 2.13, **statvfs**() populated the bits of the *f_flag* field by scanning the mount options shown in */proc/mounts*. However, starting with Linux 2.6.36, the underlying *statfs*(2) system call provides the necessary information via the *f_flags* field, and since glibc 2.13, the **statvfs**() function will use information from that field rather than scanning */proc/mounts*.

statfs(2)

NAME

stdarg, va_start, va_arg, va_end, va_copy − variable argument lists

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdarg.h>

void va_start(va_list ap, last);
type va_arg(va_list ap, type);
void va_end(va_list ap);
void va_copy(va_list dest, va_list src);
```

DESCRIPTION

A function may be called with a varying number of arguments of varying types. The include file *<stdarg.h>* declares a type *va_list* and defines three macros for stepping through a list of arguments whose number and types are not known to the called function.

The called function must declare an object of type *va_list* which is used by the macros **va_start**(), **va_arg**(), and **va_end**().

va_start()

The **va_start**() macro initializes *ap* for subsequent use by **va_arg**() and **va_end**(), and must be called first.

The argument *last* is the name of the last argument before the variable argument list, that is, the last argument of which the calling function knows the type.

Because the address of this argument may be used in the **va_start**() macro, it should not be declared as a register variable, or as a function or an array type.

va_arg()

The **va_arg**() macro expands to an expression that has the type and value of the next argument in the call. The argument *ap* is the *va_list ap* initialized by **va_start**(). Each call to **va_arg**() modifies *ap* so that the next call returns the next argument. The argument *type* is a type name specified so that the type of a pointer to an object that has the specified type can be obtained simply by adding a * to *type*.

The first use of the **va_arg**() macro after that of the **va_start**() macro returns the argument after *last*. Successive invocations return the values of the remaining arguments.

If there is no next argument, or if *type* is not compatible with the type of the actual next argument (as promoted according to the default argument promotions), random errors will occur.

If *ap* is passed to a function that uses **va_arg(***ap***,***type***),** then the value of *ap* is undefined after the return of that function.

va_end()

Each invocation of **va_start**() must be matched by a corresponding invocation of **va_end**() in the same function. After the call **va_end(***ap***)** the variable *ap* is undefined. Multiple traversals of the list, each bracketed by **va_start**() and **va_end**() are possible. **va_end**() may be a macro or a function.

va_copy()

The **va_copy**() macro copies the (previously initialized) variable argument list *src* to *dest*. The behavior is as if **va_start**() were applied to *dest* with the same *last* argument, followed by the same number of **va_arg**() invocations that was used to reach the current state of *src*.

An obvious implementation would have a *va_list* be a pointer to the stack frame of the variadic function. In such a setup (by far the most common) there seems nothing against an assignment

```
va_list aq = ap;
```

Unfortunately, there are also systems that make it an array of pointers (of length 1), and there one needs

```
va_list aq;
*aq = *ap;
```

Finally, on systems where arguments are passed in registers, it may be necessary for **va_start**() to allocate memory, store the arguments there, and also an indication of which argument is next, so that **va_arg**() can step through the list. Now **va_end**() can free the allocated memory again. To

accommodate this situation, C99 adds a macro **va_copy**(), so that the above assignment can be replaced by

```
va_list aq;
va_copy(aq, ap);
...
va_end(aq);
```

Each invocation of **va_copy**() must be matched by a corresponding invocation of **va_end**() in the same function. Some systems that do not supply **va_copy**() have **__va_copy** instead, since that was the name used in the draft proposal.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
va_start(), **va_end**(), **va_copy**()	Thread safety	MT-Safe
va_arg()	Thread safety	MT-Safe race:ap

STANDARDS

C11, POSIX.1-2008.

HISTORY

va_start()
va_arg()
va_end()
C89, POSIX.1-2001.

va_copy()
C99, POSIX.1-2001.

CAVEATS

Unlike the historical **varargs** macros, the **stdarg** macros do not permit programmers to code a function with no fixed arguments. This problem generates work mainly when converting **varargs** code to **stdarg** code, but it also creates difficulties for variadic functions that wish to pass all of their arguments on to a function that takes a *va_list* argument, such as *vfprintf*(3).

EXAMPLES

The function *foo* takes a string of format characters and prints out the argument associated with each format character based on the type.

```
#include <stdio.h>
#include <stdarg.h>

void
foo(char *fmt, ...)   /* '...' is C syntax for a variadic function */

{
    va_list ap;
    int d;
    char c;
    char *s;

    va_start(ap, fmt);
    while (*fmt)
        switch (*fmt++) {
        case 's':              /* string */
            s = va_arg(ap, char *);
            printf("string %s\n", s);
            break;
        case 'd':              /* int */
            d = va_arg(ap, int);
            printf("int %d\n", d);
            break;
        case 'c':              /* char */
```

```
                /* need a cast here since va_arg only
                   takes fully promoted types */
                c = (char) va_arg(ap, int);
                printf("char %c\n", c);
                break;
            }
        va_end(ap);
    }
```

SEE ALSO

vprintf(3), *vscanf*(3), *vsyslog*(3)

NAME

stdin, stdout, stderr − standard I/O streams

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

extern FILE *stdin;
extern FILE *stdout;
extern FILE *stderr;
```

DESCRIPTION

Under normal circumstances every UNIX program has three streams opened for it when it starts up, one for input, one for output, and one for printing diagnostic or error messages. These are typically attached to the user's terminal (see *tty*(4)) but might instead refer to files or other devices, depending on what the parent process chose to set up. (See also the "Redirection" section of *sh*(1)

The input stream is referred to as "standard input"; the output stream is referred to as "standard output"; and the error stream is referred to as "standard error". These terms are abbreviated to form the symbols used to refer to these files, namely *stdin*, *stdout*, and *stderr*.

Each of these symbols is a *stdio*(3) macro of type pointer to *FILE*, and can be used with functions like *fprintf*(3) or *fread*(3).

Since *FILE*s are a buffering wrapper around UNIX file descriptors, the same underlying files may also be accessed using the raw UNIX file interface, that is, the functions like *read*(2) and *lseek*(2).

On program startup, the integer file descriptors associated with the streams *stdin*, *stdout*, and *stderr* are 0, 1, and 2, respectively. The preprocessor symbols **STDIN_FILENO**, **STDOUT_FILENO**, and **STDERR_FILENO** are defined with these values in <*unistd.h*>. (Applying *freopen*(3) to one of these streams can change the file descriptor number associated with the stream.)

Note that mixing use of *FILE*s and raw file descriptors can produce unexpected results and should generally be avoided. (For the masochistic among you: POSIX.1, section 8.2.3, describes in detail how this interaction is supposed to work.) A general rule is that file descriptors are handled in the kernel, while stdio is just a library. This means for example, that after an *exec*(3), the child inherits all open file descriptors, but all old streams have become inaccessible.

Since the symbols *stdin*, *stdout*, and *stderr* are specified to be macros, assigning to them is nonportable. The standard streams can be made to refer to different files with help of the library function *freopen*(3), specially introduced to make it possible to reassign *stdin*, *stdout*, and *stderr*. The standard streams are closed by a call to *exit*(3) and by normal program termination.

STANDARDS

C11, POSIX.1-2008.

The standards also stipulate that these three streams shall be open at program startup.

HISTORY

C89, POSIX.1-2001.

NOTES

The stream *stderr* is unbuffered. The stream *stdout* is line-buffered when it points to a terminal. Partial lines will not appear until *fflush*(3) or *exit*(3) is called, or a newline is printed. This can produce unexpected results, especially with debugging output. The buffering mode of the standard streams (or any other stream) can be changed using the *setbuf*(3) or *setvbuf*(3) call. Note that in case *stdin* is associated with a terminal, there may also be input buffering in the terminal driver, entirely unrelated to stdio buffering. (Indeed, normally terminal input is line buffered in the kernel.) This kernel input handling can be modified using calls like *tcsetattr*(3); see also *stty*(1), and *termios*(3).

NAME

stdio − standard input/output library functions

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

FILE ****stdin*;**
FILE ****stdout*;**
FILE ****stderr*;**

DESCRIPTION

The standard I/O library provides a simple and efficient buffered stream I/O interface. Input and output is mapped into logical data streams and the physical I/O characteristics are concealed. The functions and macros are listed below; more information is available from the individual man pages.

A stream is associated with an external file (which may be a physical device) by *opening* a file, which may involve creating a new file. Creating an existing file causes its former contents to be discarded. If a file can support positioning requests (such as a disk file, as opposed to a terminal), then a *file position indicator* associated with the stream is positioned at the start of the file (byte zero), unless the file is opened with append mode. If append mode is used, it is unspecified whether the position indicator will be placed at the start or the end of the file. The position indicator is maintained by subsequent reads, writes, and positioning requests. All input occurs as if the characters were read by successive calls to the *fgetc*(3) function; all output takes place as if all characters were written by successive calls to the *fputc*(3) function.

A file is disassociated from a stream by *closing* the file. Output streams are flushed (any unwritten buffer contents are transferred to the host environment) before the stream is disassociated from the file. The value of a pointer to a *FILE* object is indeterminate after a file is closed (garbage).

A file may be subsequently reopened, by the same or another program execution, and its contents reclaimed or modified (if it can be repositioned at the start). If the main function returns to its original caller, or the *exit*(3) function is called, all open files are closed (hence all output streams are flushed) before program termination. Other methods of program termination, such as *abort*(3) do not bother about closing files properly.

At program startup, three text streams are predefined and need not be opened explicitly: *standard input* (for reading conventional input), *standard output* (for writing conventional output), and *standard error* (for writing diagnostic output). These streams are abbreviated *stdin*, *stdout*, and *stderr*. When opened, the standard error stream is not fully buffered; the standard input and output streams are fully buffered if and only if the streams do not refer to an interactive device.

Output streams that refer to terminal devices are always line buffered by default; pending output to such streams is written automatically whenever an input stream that refers to a terminal device is read. In cases where a large amount of computation is done after printing part of a line on an output terminal, it is necessary to *fflush*(3) the standard output before going off and computing so that the output will appear.

The *stdio* library is a part of the library **libc** and routines are automatically loaded as needed by *cc*(1)The SYNOPSIS sections of the following manual pages indicate which include files are to be used, what the compiler declaration for the function looks like and which external variables are of interest.

The following are defined as macros; these names may not be reused without first removing their current definitions with **#undef**: **BUFSIZ**, **EOF**, **FILENAME_MAX**, **FOPEN_MAX**, **L_cuserid**, **L_ctermid**, **L_tmpnam**, **NULL**, **SEEK_END**, **SEEK_SET**, **SEEK_CUR**, **TMP_MAX**, **clearerr**, **feof**, **ferror**, **fileno**, **getc**, **getchar**, **putc**, **putchar**, **stderr**, **stdin**, **stdout**. Function versions of the macro functions **feof**, **ferror**, **clearerr**, **fileno**, **getc**, **getchar**, **putc**, and **putchar** exist and will be used if the macros definitions are explicitly removed.

List of functions

Function	Description
clearerr(3)	check and reset stream status

fclose(3)	close a stream
fdopen(3)	stream open functions
feof(3)	check and reset stream status
ferror(3)	check and reset stream status
fflush(3)	flush a stream
fgetc(3)	get next character or word from input stream
fgetpos(3)	reposition a stream
fgets(3)	get a line from a stream
fileno(3)	return the integer descriptor of the argument stream
fmemopen(3)	open memory as stream
fopen(3)	stream open functions
fopencookie(3)	open a custom stream
fprintf(3)	formatted output conversion
fpurge(3)	flush a stream
fputc(3)	output a character or word to a stream
fputs(3)	output a line to a stream
fread(3)	binary stream input/output
freopen(3)	stream open functions
fscanf(3)	input format conversion
fseek(3)	reposition a stream
fsetpos(3)	reposition a stream
ftell(3)	reposition a stream
fwrite(3)	binary stream input/output
getc(3)	get next character or word from input stream
getchar(3)	get next character or word from input stream
gets(3)	get a line from a stream
getw(3)	get next character or word from input stream
mktemp(3)	make temporary filename (unique)
open_memstream(3)	open a dynamic memory buffer stream
open_wmemstream(3)	open a dynamic memory buffer stream
perror(3)	system error messages
printf(3)	formatted output conversion
putc(3)	output a character or word to a stream
putchar(3)	output a character or word to a stream
puts(3)	output a line to a stream
putw(3)	output a character or word to a stream
remove(3)	remove directory entry
rewind(3)	reposition a stream
scanf(3)	input format conversion
setbuf(3)	stream buffering operations
setbuffer(3)	stream buffering operations
setlinebuf(3)	stream buffering operations
setvbuf(3)	stream buffering operations
sprintf(3)	formatted output conversion
sscanf(3)	input format conversion
strerror(3)	system error messages
sys_errlist(3)	system error messages
sys_nerr(3)	system error messages
tempnam(3)	temporary file routines
tmpfile(3)	temporary file routines
tmpnam(3)	temporary file routines
ungetc(3)	un-get character from input stream
vfprintf(3)	formatted output conversion
vfscanf(3)	input format conversion
vprintf(3)	formatted output conversion
vscanf(3)	input format conversion
vsprintf(3)	formatted output conversion
vsscanf(3)	input format conversion

NAME

__fbufsize, __flbf, __fpending, __fpurge, __freadable, __freading, __fsetlocking, __fwritable, __fwriting, _flushlbf − interfaces to stdio FILE structure

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>
#include <stdio_ext.h>

size_t __fbufsize(FILE *stream);
size_t __fpending(FILE *stream);
int __flbf(FILE *stream);
int __freadable(FILE *stream);
int __fwritable(FILE *stream);
int __freading(FILE *stream);
int __fwriting(FILE *stream);
int __fsetlocking(FILE *stream, int type);
void _flushlbf(void);
void __fpurge(FILE *stream);
```

DESCRIPTION

Solaris introduced routines to allow portable access to the internals of the *FILE* structure, and glibc also implemented these.

The **__fbufsize**() function returns the size of the buffer currently used by the given stream.

The **__fpending**() function returns the number of bytes in the output buffer. For wide-oriented streams the unit is wide characters. This function is undefined on buffers in reading mode, or opened read-only.

The **__flbf**() function returns a nonzero value if the stream is line-buffered, and zero otherwise.

The **__freadable**() function returns a nonzero value if the stream allows reading, and zero otherwise.

The **__fwritable**() function returns a nonzero value if the stream allows writing, and zero otherwise.

The **__freading**() function returns a nonzero value if the stream is read-only, or if the last operation on the stream was a read operation, and zero otherwise.

The **__fwriting**() function returns a nonzero value if the stream is write-only (or append-only), or if the last operation on the stream was a write operation, and zero otherwise.

The **__fsetlocking**() function can be used to select the desired type of locking on the stream. It returns the current type. The *type* argument can take the following three values:

FSETLOCKING_INTERNAL
: Perform implicit locking around every operation on the given stream (except for the *_unlocked ones). This is the default.

FSETLOCKING_BYCALLER
: The caller will take care of the locking (possibly using *flockfile*(3) in case there is more than one thread), and the stdio routines will not do locking until the state is reset to **FSETLOCKING_INTERNAL**.

FSETLOCKING_QUERY
: Don't change the type of locking. (Only return it.)

The **_flushlbf**() function flushes all line-buffered streams. (Presumably so that output to a terminal is forced out, say before reading keyboard input.)

The **__fpurge**() function discards the contents of the stream's buffer.

NAME

stpncpy, strncpy − fill a fixed-size buffer with non-null bytes from a string, padding with null bytes as needed

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strncpy(char dst[restrict .dsize], const char *restrict src,
        size_t dsize);
char *stpncpy(char dst[restrict .dsize], const char *restrict src,
        size_t dsize);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

stpncpy():
  Since glibc 2.10:
    _POSIX_C_SOURCE >= 200809L
  Before glibc 2.10:
    _GNU_SOURCE

DESCRIPTION

These functions copy non-null bytes from the string pointed to by *src* into the array pointed to by *dst*. If the source has too few non-null bytes to fill the destination, the functions pad the destination with trailing null bytes. If the destination buffer, limited by its size, isn't large enough to hold the copy, the resulting character sequence is truncated. For the difference between the two functions, see RETURN VALUE.

An implementation of these functions might be:

```
char *
strncpy(char *restrict dst, const char *restrict src, size_t dsize)
{
    stpncpy(dst, src, dsize);
    return dst;
}

char *
stpncpy(char *restrict dst, const char *restrict src, size_t dsize)
{
    size_t  dlen;

    dlen = strnlen(src, dsize);
    return memset(mempcpy(dst, src, dlen), 0, dsize - dlen);
}
```

RETURN VALUE

strncpy()
: returns *dst*.

stpncpy()
: returns a pointer to one after the last character in the destination character sequence.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
stpncpy(), **strncpy**()	Thread safety	MT-Safe

STANDARDS

strncpy()
: C11, POSIX.1-2008.

stpncpy()
POSIX.1-2008.

HISTORY

strncpy()
C89, POSIX.1-2001, SVr4, 4.3BSD.

stpncpy()
glibc 1.07. POSIX.1-2008.

CAVEATS

The name of these functions is confusing. These functions produce a null-padded character sequence, not a string (see *string_copying*(7)). For example:

```
strncpy(buf, "1", 5);       // { '1',   0,   0,   0,   0 }
strncpy(buf, "1234", 5);    // { '1', '2', '3', '4',   0 }
strncpy(buf, "12345", 5);   // { '1', '2', '3', '4', '5' }
strncpy(buf, "123456", 5);  // { '1', '2', '3', '4', '5' }
```

It's impossible to distinguish truncation by the result of the call, from a character sequence that just fits the destination buffer; truncation should be detected by comparing the length of the input string with the size of the destination buffer.

If you're going to use this function in chained calls, it would be useful to develop a similar function that accepts a pointer to the end (one after the last element) of the destination buffer instead of its size.

EXAMPLES

```
#include <err.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(void)
{
    char    *p;
    char    buf1[20];
    char    buf2[20];
    size_t  len;

    if (sizeof(buf2) < strlen("Hello world!"))
        errx("strncpy: truncating character sequence");
    strncpy(buf2, "Hello world!", sizeof(buf2));
    len = strnlen(buf2, sizeof(buf2));

    printf("[len = %zu]: ", len);
    fwrite(buf2, 1, len, stdout);
    putchar('\n');

    if (sizeof(buf1) < strlen("Hello world!"))
        errx("stpncpy: truncating character sequence");
    p = stpncpy(buf1, "Hello world!", sizeof(buf1));
    len = p - buf1;

    printf("[len = %zu]: ", len);
    fwrite(buf1, 1, len, stdout);
    putchar('\n');

    exit(EXIT_SUCCESS);
}
```

NAME

strcasecmp, strncasecmp − compare two strings ignoring case

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <strings.h>

int strcasecmp(const char *s1, const char *s2);
int strncasecmp(const char s1[.n], const char s2[.n], size_t n);
```

DESCRIPTION

The **strcasecmp**() function performs a byte-by-byte comparison of the strings *s1* and *s2*, ignoring the case of the characters. It returns an integer less than, equal to, or greater than zero if *s1* is found, respectively, to be less than, to match, or be greater than *s2*.

The **strncasecmp**() function is similar, except that it compares no more than *n* bytes of *s1* and *s2*.

RETURN VALUE

The **strcasecmp**() and **strncasecmp**() functions return an integer less than, equal to, or greater than zero if *s1* is, after ignoring case, found to be less than, to match, or be greater than *s2*, respectively.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strcasecmp(), **strncasecmp**()	Thread safety	MT-Safe locale

STANDARDS

POSIX.1-2008.

HISTORY

4.4BSD, POSIX.1-2001.

The **strcasecmp**() and **strncasecmp**() functions first appeared in 4.4BSD, where they were declared in <*string.h*>. Thus, for reasons of historical compatibility, the glibc <*string.h*> header file also declares these functions, if the **_DEFAULT_SOURCE** (or, in glibc 2.19 and earlier, **_BSD_SOURCE**) feature test macro is defined.

The POSIX.1-2008 standard says of these functions:

> When the **LC_CTYPE** category of the locale being used is from the POSIX locale, these functions shall behave as if the strings had been converted to lowercase and then a byte comparison performed. Otherwise, the results are unspecified.

NAME

strchr, strrchr, strchrnul − locate character in string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strchr(const char *s, int c);
char *strrchr(const char *s, int c);

#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>

char *strchrnul(const char *s, int c);
```

DESCRIPTION

The **strchr**() function returns a pointer to the first occurrence of the character *c* in the string *s*.

The **strrchr**() function returns a pointer to the last occurrence of the character *c* in the string *s*.

The **strchrnul**() function is like **strchr**() except that if *c* is not found in *s*, then it returns a pointer to the null byte at the end of *s*, rather than NULL.

Here "character" means "byte"; these functions do not work with wide or multibyte characters.

RETURN VALUE

The **strchr**() and **strrchr**() functions return a pointer to the matched character or NULL if the character is not found. The terminating null byte is considered part of the string, so that if *c* is specified as '\0', these functions return a pointer to the terminator.

The **strchrnul**() function returns a pointer to the matched character, or a pointer to the null byte at the end of *s* (i.e., *s+strlen(s)*) if the character is not found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strcmp, strncmp − compare two strings

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

int strcmp(const char *s1, const char *s2);
int strncmp(const char s1[.n], const char s2[.n], size_t n);
```

DESCRIPTION

The **strcmp**() function compares the two strings *s1* and *s2*. The locale is not taken into account (for a locale-aware comparison, see *strcoll*(3)). The comparison is done using unsigned characters.

strcmp() returns an integer indicating the result of the comparison, as follows:

- 0, if the *s1* and *s2* are equal;
- a negative value if *s1* is less than *s2*;
- a positive value if *s1* is greater than *s2*.

The **strncmp**() function is similar, except it compares only the first (at most) *n* bytes of *s1* and *s2*.

RETURN VALUE

The **strcmp**() and **strncmp**() functions return an integer less than, equal to, or greater than zero if *s1* (or the first *n* bytes thereof) is found, respectively, to be less than, to match, or be greater than *s2*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strcmp(), **strncmp**()	Thread safety	MT-Safe

VERSIONS

POSIX.1 specifies only that:

> The sign of a nonzero return value shall be determined by the sign of the difference between the values of the first pair of bytes (both interpreted as type *unsigned char*) that differ in the strings being compared.

In glibc, as in most other implementations, the return value is the arithmetic result of subtracting the last compared byte in *s2* from the last compared byte in *s1*. (If the two characters are equal, this difference is 0.)

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD.

EXAMPLES

The program below can be used to demonstrate the operation of **strcmp**() (when given two arguments) and **strncmp**() (when given three arguments). First, some examples using **strcmp**():

```
$ ./string_comp ABC ABC
<str1> and <str2> are equal
$ ./string_comp ABC AB      # 'C' is ASCII 67; 'C' - '\0' = 67
<str1> is greater than <str2> (67)
$ ./string_comp ABA ABZ     # 'A' is ASCII 65; 'Z' is ASCII 90
<str1> is less than <str2> (-25)
$ ./string_comp ABJ ABC
<str1> is greater than <str2> (7)
$ ./string_comp $'\201' A   # 0201 - 0101 = 0100 (or 64 decimal)
<str1> is greater than <str2> (64)
```

The last example uses *bash*(1)-specific syntax to produce a string containing an 8-bit ASCII code; the result demonstrates that the string comparison uses unsigned characters.

And then some examples using **strncmp**():

```
$ ./string_comp ABC AB 3
<str1> is greater than <str2> (67)
$ ./string_comp ABC AB 2
<str1> and <str2> are equal in the first 2 bytes
```

Program source

```
/* string_comp.c

   Licensed under GNU General Public License v2 or later.
*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(int argc, char *argv[])
{
    int res;

    if (argc < 3) {
        fprintf(stderr, "Usage: %s <str1> <str2> [<len>]\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    if (argc == 3)
        res = strcmp(argv[1], argv[2]);
    else
        res = strncmp(argv[1], argv[2], atoi(argv[3]));

    if (res == 0) {
        printf("<str1> and <str2> are equal");
        if (argc > 3)
            printf(" in the first %d bytes\n", atoi(argv[3]));
        printf("\n");
    } else if (res < 0) {
        printf("<str1> is less than <str2> (%d)\n", res);
    } else {
        printf("<str1> is greater than <str2> (%d)\n", res);
    }

    exit(EXIT_SUCCESS);
}
```

NAME

strcoll − compare two strings using the current locale

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

int strcoll(const char *_s1_, const char *_s2_);

DESCRIPTION

The **strcoll**() function compares the two strings *s1* and *s2*. It returns an integer less than, equal to, or greater than zero if *s1* is found, respectively, to be less than, to match, or be greater than *s2*. The comparison is based on strings interpreted as appropriate for the program's current locale for category **LC_COLLATE**. (See *setlocale*(3).)

RETURN VALUE

The **strcoll**() function returns an integer less than, equal to, or greater than zero if *s1* is found, respectively, to be less than, to match, or be greater than *s2*, when both are interpreted as appropriate for the current locale.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strcoll()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD.

NOTES

In the *POSIX* or *C* locales **strcoll**() is equivalent to *strcmp*(3).

SEE ALSO

memcmp(3), *setlocale*(3), *strcasecmp*(3), *strcmp*(3), *string*(3), *strxfrm*(3)

NAME

stpcpy, strcpy, strcat − copy or catenate a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *stpcpy(char *restrict dst, const char *restrict src);
char *strcpy(char *restrict dst, const char *restrict src);
char *strcat(char *restrict dst, const char *restrict src);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

stpcpy():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

stpcpy()
strcpy()
These functions copy the string pointed to by *src*, into a string at the buffer pointed to by *dst*. The programmer is responsible for allocating a destination buffer large enough, that is, *strlen(src) + 1*. For the difference between the two functions, see RETURN VALUE.

strcat() This function catenates the string pointed to by *src*, after the string pointed to by *dst* (overwriting its terminating null byte). The programmer is responsible for allocating a destination buffer large enough, that is, *strlen(dst) + strlen(src) + 1*.

An implementation of these functions might be:

```
char *
stpcpy(char *restrict dst, const char *restrict src)
{
    char  *p;

    p = mempcpy(dst, src, strlen(src));
    *p = '\0';

    return p;
}

char *
strcpy(char *restrict dst, const char *restrict src)
{
    stpcpy(dst, src);
    return dst;
}

char *
strcat(char *restrict dst, const char *restrict src)
{
    stpcpy(dst + strlen(dst), src);
    return dst;
}
```

RETURN VALUE

stpcpy()
This function returns a pointer to the terminating null byte of the copied string.

strcpy()
strcat() These functions return *dst*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
stpcpy(), **strcpy**(), **strcat**()	Thread safety	MT-Safe

STANDARDS

stpcpy()
POSIX.1-2008.

strcpy()
strcat() C11, POSIX.1-2008.

STANDARDS

stpcpy()
POSIX.1-2008.

strcpy()
strcat() POSIX.1-2001, C89, SVr4, 4.3BSD.

CAVEATS

The strings *src* and *dst* may not overlap.

If the destination buffer is not large enough, the behavior is undefined. See **_FORTIFY_SOURCE** in *feature_test_macros*(7).

strcat() can be very inefficient. Read about Shlemiel the painter.

EXAMPLES

```
#include <err.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(void)
{
    char    *p;
    char    *buf1;
    char    *buf2;
    size_t  len, maxsize;

    maxsize = strlen("Hello ") + strlen("world") + strlen("!") + 1;
    buf1 = malloc(sizeof(*buf1) * maxsize);
    if (buf1 == NULL)
        err(EXIT_FAILURE, "malloc()");
    buf2 = malloc(sizeof(*buf2) * maxsize);
    if (buf2 == NULL)
        err(EXIT_FAILURE, "malloc()");

    p = buf1;
    p = stpcpy(p, "Hello ");
    p = stpcpy(p, "world");
    p = stpcpy(p, "!");
    len = p - buf1;

    printf("[len = %zu]: ", len);
    puts(buf1);  // "Hello world!"
    free(buf1);

    strcpy(buf2, "Hello ");
    strcat(buf2, "world");
```

```
        strcat(buf2, "!");
        len = strlen(buf2);

        printf("[len = %zu]: ", len);
        puts(buf2);  // "Hello world!"
        free(buf2);

        exit(EXIT_SUCCESS);
    }
```

SEE ALSO

strdup(3), *string*(3), *wcscpy*(3), *string_copying*(7)

NAME

strdup, strndup, strdupa, strndupa − duplicate a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strdup(const char *s);

char *strndup(const char s[.n], size_t n);
char *strdupa(const char *s);
char *strndupa(const char s[.n], size_t n);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strdup():
_XOPEN_SOURCE >= 500
|| /* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

strndup():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

strdupa(), **strndupa**():
_GNU_SOURCE

DESCRIPTION

The **strdup**() function returns a pointer to a new string which is a duplicate of the string *s*. Memory for the new string is obtained with *malloc*(3), and can be freed with *free*(3).

The **strndup**() function is similar, but copies at most *n* bytes. If *s* is longer than *n*, only *n* bytes are copied, and a terminating null byte ('\0') is added.

strdupa() and **strndupa**() are similar, but use *alloca*(3) to allocate the buffer.

RETURN VALUE

On success, the **strdup**() function returns a pointer to the duplicated string. It returns NULL if insufficient memory was available, with *errno* set to indicate the error.

ERRORS

ENOMEM
Insufficient memory available to allocate duplicate string.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strerror, strerrorname_np, strerrordesc_np, strerror_r, strerror_l − return string describing error number

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strerror(int errnum);
const char *strerrorname_np(int errnum);
const char *strerrordesc_np(int errnum);

int strerror_r(int errnum, char buf[.buflen], size_t buflen);
        /* XSI-compliant */

char *strerror_r(int errnum, char buf[.buflen], size_t buflen);
        /* GNU-specific */

char *strerror_l(int errnum, locale_t locale);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strerrorname_np(), **strerrordesc_np**():
_GNU_SOURCE

strerror_r():
The XSI-compliant version is provided if:
(_POSIX_C_SOURCE >= 200112L) && ! _GNU_SOURCE
Otherwise, the GNU-specific version is provided.

DESCRIPTION

The **strerror**() function returns a pointer to a string that describes the error code passed in the argument *errnum*, possibly using the **LC_MESSAGES** part of the current locale to select the appropriate language. (For example, if *errnum* is **EINVAL**, the returned description will be "Invalid argument".) This string must not be modified by the application, and the returned pointer will be invalidated on a subsequent call to **strerror**() or **strerror_l**(), or if the thread that obtained the string exits. No other library function, including *perror*(3), will modify this string.

Like **strerror**(), the **strerrordesc_np**() function returns a pointer to a string that describes the error code passed in the argument *errnum*, with the difference that the returned string is not translated according to the current locale.

The **strerrorname_np**() function returns a pointer to a string containing the name of the error code passed in the argument *errnum*. For example, given **EPERM** as an argument, this function returns a pointer to the string "EPERM". Given **0** as an argument, this function returns a pointer to the string "0".

strerror_r()

strerror_r() is like **strerror**(), but might use the supplied buffer *buf* instead of allocating one internally. This function is available in two versions: an XSI-compliant version specified in POSIX.1-2001 (available since glibc 2.3.4, but not POSIX-compliant until glibc 2.13), and a GNU-specific version (available since glibc 2.0). The XSI-compliant version is provided with the feature test macros settings shown in the SYNOPSIS; otherwise the GNU-specific version is provided. If no feature test macros are explicitly defined, then (since glibc 2.4) **_POSIX_C_SOURCE** is defined by default with the value 200112L, so that the XSI-compliant version of **strerror_r**() is provided by default.

The XSI-compliant **strerror_r**() is preferred for portable applications. It returns the error string in the user-supplied buffer *buf* of length *buflen*.

The GNU-specific **strerror_r**() returns a pointer to a string containing the error message. This may be either a pointer to a string that the function stores in *buf*, or a pointer to some (immutable) static string (in which case *buf* is unused). If the function stores a string in *buf*, then at most *buflen* bytes are stored (the string may be truncated if *buflen* is too small and *errnum* is unknown). The string always includes a terminating null byte ('\0').

strerror_l()

strerror_l() is like **strerror**(), but maps *errnum* to a locale-dependent error message in the locale specified by *locale*. The behavior of **strerror_l**() is undefined if *locale* is the special locale object **LC_GLOBAL_LOCALE** or is not a valid locale object handle.

RETURN VALUE

The **strerror**(), **strerror_l**(), and the GNU-specific **strerror_r**() functions return the appropriate error description string, or an "Unknown error nnn" message if the error number is unknown.

On success, **strerrorname_np**() and **strerrordesc_np**() return the appropriate error description string. If *errnum* is an invalid error number, these functions return NULL.

The XSI-compliant **strerror_r**() function returns 0 on success. On error, a (positive) error number is returned (since glibc 2.13), or −1 is returned and *errno* is set to indicate the error (before glibc 2.13).

POSIX.1-2001 and POSIX.1-2008 require that a successful call to **strerror**() or **strerror_l**() shall leave *errno* unchanged, and note that, since no function return value is reserved to indicate an error, an application that wishes to check for errors should initialize *errno* to zero before the call, and then check *errno* after the call.

ERRORS

EINVAL
The value of *errnum* is not a valid error number.

ERANGE
Insufficient storage was supplied to contain the error description string.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strerror()	Thread safety	MT-Safe
strerrorname_np(), **strerrordesc_np**()	Thread safety	MT-Safe
strerror_r(), **strerror_l**()	Thread safety	MT-Safe

Before glibc 2.32, **strerror**() is not MT-Safe.

STANDARDS

strerror()
C11, POSIX.1-2008.

strerror_r()
strerror_l()
POSIX.1-2008.

strerrorname_np()
strerrordesc_np()
GNU.

POSIX.1-2001 permits **strerror**() to set *errno* if the call encounters an error, but does not specify what value should be returned as the function result in the event of an error. On some systems, **strerror**() returns NULL if the error number is unknown. On other systems, **strerror**() returns a string something like "Error nnn occurred" and sets *errno* to **EINVAL** if the error number is unknown. C99 and POSIX.1-2008 require the return value to be non-NULL.

HISTORY

strerror()
POSIX.1-2001, C89.

strerror_r()
POSIX.1-2001.

strerror_l()
glibc 2.6. POSIX.1-2008.

strerrorname_np()

strerrordesc_np()
glibc 2.32.

NOTES

strerrorname_np() and **strerrordesc_np**() are thread-safe and async-signal-safe.

NAME

strfmon, strfmon_l − convert monetary value to a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <monetary.h>

ssize_t strfmon(char s[restrict .max], size_t max,
                const char *restrict format, ...);
ssize_t strfmon_l(char s[restrict .max], size_t max, locale_t locale,
                const char *restrict format, ...);
```

DESCRIPTION

The **strfmon**() function formats the specified monetary amount according to the current locale and format specification *format* and places the result in the character array *s* of size *max*.

The **strfmon_l**() function performs the same task, but uses the locale specified by *locale*. The behavior of **strfmon_l**() is undefined if *locale* is the special locale object **LC_GLOBAL_LOCALE** (see *duplocale*(3)) or is not a valid locale object handle.

Ordinary characters in *format* are copied to *s* without conversion. Conversion specifiers are introduced by a '%' character. Immediately following it there can be zero or more of the following flags:

=*f* The single-byte character *f* is used as the numeric fill character (to be used with a left precision, see below). When not specified, the space character is used.

^ Do not use any grouping characters that might be defined for the current locale. By default, grouping is enabled.

(or **+** The (flag indicates that negative amounts should be enclosed between parentheses. The + flag indicates that signs should be handled in the default way, that is, amounts are preceded by the locale's sign indication, for example, nothing for positive, "−" for negative.

! Omit the currency symbol.

− Left justify all fields. The default is right justification.

Next, there may be a field width: a decimal digit string specifying a minimum field width in bytes. The default is 0. A result smaller than this width is padded with spaces (on the left, unless the left-justify flag was given).

Next, there may be a left precision of the form "#" followed by a decimal digit string. If the number of digits left of the radix character is smaller than this, the representation is padded on the left with the numeric fill character. Grouping characters are not counted in this field width.

Next, there may be a right precision of the form "." followed by a decimal digit string. The amount being formatted is rounded to the specified number of digits prior to formatting. The default is specified in the *frac_digits* and *int_frac_digits* items of the current locale. If the right precision is 0, no radix character is printed. (The radix character here is determined by **LC_MONETARY**, and may differ from that specified by **LC_NUMERIC**.)

Finally, the conversion specification must be ended with a conversion character. The three conversion characters are

% (In this case, the entire specification must be exactly "%%".) Put a '%' character in the result string.

i One argument of type *double* is converted using the locale's international currency format.

n One argument of type *double* is converted using the locale's national currency format.

RETURN VALUE

The **strfmon**() function returns the number of characters placed in the array *s*, not including the terminating null byte, provided the string, including the terminating null byte, fits. Otherwise, it sets *errno* to **E2BIG**, returns −1, and the contents of the array is undefined.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strfmon()	Thread safety	MT-Safe locale
strfmon_l()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

EXAMPLES

The call

```
strfmon(buf, sizeof(buf), "[%^=*#6n] [%=*#6i]",
        1234.567, 1234.567);
```

outputs

```
[€ **1234,57] [EUR **1 234,57]
```

in the *nl_NL* locale. The *de_DE*, *de_CH*, *en_AU*, and *en_GB* locales yield

```
[ **1234,57 €] [ **1.234,57 EUR]
[ Fr. **1234.57] [ CHF **1'234.57]
[ $**1234.57] [ AUD**1,234.57]
[ £**1234.57] [ GBP**1,234.57]
```

NAME

strfromd, strfromf, strfroml − convert a floating-point value into a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

int strfromd(char str[restrict .n], size_t n,
        const char *restrict format, double fp);
int strfromf(char str[restrict .n], size_t n,
        const char *restrict format, float fp);
int strfroml(char str[restrict .n], size_t n,
        const char *restrict format, long double fp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strfromd(), **strfromf**(), **strfroml**():
__STDC_WANT_IEC_60559_BFP_EXT__

DESCRIPTION

These functions convert a floating-point value, *fp*, into a string of characters, *str*, with a configurable *format* string. At most *n* characters are stored into *str*.

The terminating null byte ('\0') is written if and only if *n* is sufficiently large, otherwise the written string is truncated at *n* characters.

The **strfromd**(), **strfromf**(), and **strfroml**() functions are equivalent to

```
snprintf(str, n, format, fp);
```

except for the *format* string.

Format of the format string

The *format* string must start with the character '%'. This is followed by an optional precision which starts with the period character (.), followed by an optional decimal integer. If no integer is specified after the period character, a precision of zero is used. Finally, the format string should have one of the conversion specifiers **a**, **A**, **e**, **E**, **f**, **F**, **g**, or **G**.

The conversion specifier is applied based on the floating-point type indicated by the function suffix. Therefore, unlike **snprintf**(), the format string does not have a length modifier character. See *snprintf*(3) for a detailed description of these conversion specifiers.

The implementation conforms to the C99 standard on conversion of NaN and infinity values:

> If *fp* is a NaN, +NaN, or −NaN, and **f** (or **a**, **e**, **g**) is the conversion specifier, the conversion is to "nan", "nan", or "−nan", respectively. If **F** (or **A**, **E**, **G**) is the conversion specifier, the conversion is to "NAN" or "−NAN".
>
> Likewise if *fp* is infinity, it is converted to [−]inf or [−]INF.

A malformed *format* string results in undefined behavior.

RETURN VALUE

The **strfromd**(), **strfromf**(), and **strfroml**() functions return the number of characters that would have been written in *str* if *n* had enough space, not counting the terminating null byte. Thus, a return value of *n* or greater means that the output was truncated.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7) and the **POSIX Safety Concepts** section in GNU C Library manual.

Interface	Attribute	Value
strfromd(), **strfromf**(), **strfroml**()	Thread safety	MT-Safe locale
	Async-signal safety	AS-Unsafe heap
	Async-cancel safety	AC-Unsafe mem

Note: these attributes are preliminary.

STANDARDS

ISO/IEC TS 18661-1.

VERSIONS

strfromd()
strfromf()
strfroml()
glibc 2.25.

NOTES

These functions take account of the **LC_NUMERIC** category of the current locale.

EXAMPLES

To convert the value 12.1 as a float type to a string using decimal notation, resulting in "12.100000":

```
#define __STDC_WANT_IEC_60559_BFP_EXT__
#include <stdlib.h>
int ssize = 10;
char s[ssize];
strfromf(s, ssize, "%f", 12.1);
```

To convert the value 12.3456 as a float type to a string using decimal notation with two digits of precision, resulting in "12.35":

```
#define __STDC_WANT_IEC_60559_BFP_EXT__
#include <stdlib.h>
int ssize = 10;
char s[ssize];
strfromf(s, ssize, "%.2f", 12.3456);
```

To convert the value 12.345e19 as a double type to a string using scientific notation with zero digits of precision, resulting in "1E+20":

```
#define __STDC_WANT_IEC_60559_BFP_EXT__
#include <stdlib.h>
int ssize = 10;
char s[ssize];
strfromd(s, ssize, "%.E", 12.345e19);
```

NAME

strfry − randomize a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>

char *strfry(char *string);
```

DESCRIPTION

The **strfry**() function randomizes the contents of *string* by randomly swapping characters in the string. The result is an anagram of *string*.

RETURN VALUE

The **strfry**() functions returns a pointer to the randomized string.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strftime − format date and time

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <time.h>

size_t strftime(char s[restrict .max], size_t max,
                const char *restrict format,
                const struct tm *restrict tm);

size_t strftime_l(char s[restrict .max], size_t max,
                const char *restrict format,
                const struct tm *restrict tm,
                locale_t locale);
```

DESCRIPTION

The **strftime**() function formats the broken-down time *tm* according to the format specification *format* and places the result in the character array *s* of size *max*. The broken-down time structure *tm* is defined in <*time.h*>. See also *ctime*(3).

The format specification is a null-terminated string and may contain special character sequences called *conversion specifications*, each of which is introduced by a '%' character and terminated by some other character known as a *conversion specifier character*. All other character sequences are *ordinary character sequences*.

The characters of ordinary character sequences (including the null byte) are copied verbatim from *format* to *s*. However, the characters of conversion specifications are replaced as shown in the list below. In this list, the field(s) employed from the *tm* structure are also shown.

%a The abbreviated name of the day of the week according to the current locale. (Calculated from *tm_wday*.) (The specific names used in the current locale can be obtained by calling *nl_langinfo*(3) with **ABDAY_**{**1**–**7**} as an argument.)

%A The full name of the day of the week according to the current locale. (Calculated from *tm_wday*.) (The specific names used in the current locale can be obtained by calling *nl_langinfo*(3) with **DAY_**{**1**–**7**} as an argument.)

%b The abbreviated month name according to the current locale. (Calculated from *tm_mon*.) (The specific names used in the current locale can be obtained by calling *nl_langinfo*(3) with **ABMON_**{**1**–**12**} as an argument.)

%B The full month name according to the current locale. (Calculated from *tm_mon*.) (The specific names used in the current locale can be obtained by calling *nl_langinfo*(3) with **MON_**{**1**–**12**} as an argument.)

%c The preferred date and time representation for the current locale. (The specific format used in the current locale can be obtained by calling *nl_langinfo*(3) with **D_T_FMT** as an argument for the **%c** conversion specification, and with **ERA_D_T_FMT** for the **%Ec** conversion specification.) (In the POSIX locale this is equivalent to **%a %b %e %H:%M:%S %Y**.)

%C The century number (year/100) as a 2-digit integer. (SU) (The **%EC** conversion specification corresponds to the name of the era.) (Calculated from *tm_year*.)

%d The day of the month as a decimal number (range 01 to 31). (Calculated from *tm_mday*.)

%D Equivalent to **%m/%d/%y**. (Yecch—for Americans only. Americans should note that in other countries **%d/%m/%y** is rather common. This means that in international context this format is ambiguous and should not be used.) (SU)

%e Like **%d**, the day of the month as a decimal number, but a leading zero is replaced by a space. (SU) (Calculated from *tm_mday*.)

%E Modifier: use alternative ("era-based") format, see below. (SU)

%F Equivalent to **%Y−%m−%d** (the ISO 8601 date format). (C99)

%G The ISO 8601 week-based year (see NOTES) with century as a decimal number. The 4-digit year corresponding to the ISO week number (see **%V**). This has the same format and value as **%Y**, except that if the ISO week number belongs to the previous or next year, that year is used instead. (TZ) (Calculated from *tm_year*, *tm_yday*, and *tm_wday*.)

%g Like **%G**, but without century, that is, with a 2-digit year (00–99). (TZ) (Calculated from *tm_year*, *tm_yday*, and *tm_wday*.)

%h Equivalent to **%b**. (SU)

%H The hour as a decimal number using a 24-hour clock (range 00 to 23). (Calculated from *tm_hour*.)

%I The hour as a decimal number using a 12-hour clock (range 01 to 12). (Calculated from *tm_hour*.)

%j The day of the year as a decimal number (range 001 to 366). (Calculated from *tm_yday*.)

%k The hour (24-hour clock) as a decimal number (range 0 to 23); single digits are preceded by a blank. (See also **%H**.) (Calculated from *tm_hour*.) (TZ)

%l The hour (12-hour clock) as a decimal number (range 1 to 12); single digits are preceded by a blank. (See also **%I**.) (Calculated from *tm_hour*.) (TZ)

%m The month as a decimal number (range 01 to 12). (Calculated from *tm_mon*.)

%M The minute as a decimal number (range 00 to 59). (Calculated from *tm_min*.)

%n A newline character. (SU)

%O Modifier: use alternative numeric symbols, see below. (SU)

%p Either "AM" or "PM" according to the given time value, or the corresponding strings for the current locale. Noon is treated as "PM" and midnight as "AM". (Calculated from *tm_hour*.) (The specific string representations used for "AM" and "PM" in the current locale can be obtained by calling *nl_langinfo*(3) with **AM_STR** and **PM_STR**, respectively.)

%P Like **%p** but in lowercase: "am" or "pm" or a corresponding string for the current locale. (Calculated from *tm_hour*.) (GNU)

%r The time in a.m. or p.m. notation. (SU) (The specific format used in the current locale can be obtained by calling *nl_langinfo*(3) with **T_FMT_AMPM** as an argument.) (In the POSIX locale this is equivalent to **%I:%M:%S %p**.)

%R The time in 24-hour notation (**%H:%M**). (SU) For a version including the seconds, see **%T** below.

%s The number of seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC). (TZ) (Calculated from *mktime(tm)*.)

%S The second as a decimal number (range 00 to 60). (The range is up to 60 to allow for occasional leap seconds.) (Calculated from *tm_sec*.)

%t A tab character. (SU)

%T The time in 24-hour notation (**%H:%M:%S**). (SU)

%u The day of the week as a decimal, range 1 to 7, Monday being 1. See also **%w**. (Calculated from *tm_wday*.) (SU)

%U The week number of the current year as a decimal number, range 00 to 53, starting with the first Sunday as the first day of week 01. See also **%V** and **%W**. (Calculated from *tm_yday* and *tm_wday*.)

%V The ISO 8601 week number (see NOTES) of the current year as a decimal number, range 01 to 53, where week 1 is the first week that has at least 4 days in the new year. See also **%U** and **%W**. (Calculated from *tm_year*, *tm_yday*, and *tm_wday*.) (SU)

%w The day of the week as a decimal, range 0 to 6, Sunday being 0. See also **%u**. (Calculated from *tm_wday*.)

%W The week number of the current year as a decimal number, range 00 to 53, starting with the first Monday as the first day of week 01. (Calculated from *tm_yday* and *tm_wday*.)

%x The preferred date representation for the current locale without the time. (The specific format used in the current locale can be obtained by calling *nl_langinfo*(3) with **D_FMT** as an argument for the **%x** conversion specification, and with **ERA_D_FMT** for the **%Ex** conversion specification.) (In the POSIX locale this is equivalent to **%m/%d/%y**.)

%X The preferred time representation for the current locale without the date. (The specific format used in the current locale can be obtained by calling *nl_langinfo*(3) with **T_FMT** as an argument for the **%X** conversion specification, and with **ERA_T_FMT** for the **%EX** conversion specification.) (In the POSIX locale this is equivalent to **%H:%M:%S**.)

%y The year as a decimal number without a century (range 00 to 99). (The **%Ey** conversion specification corresponds to the year since the beginning of the era denoted by the **%EC** conversion specification.) (Calculated from *tm_year*)

%Y The year as a decimal number including the century. (The **%EY** conversion specification corresponds to the full alternative year representation.) (Calculated from *tm_year*)

%z The *+hhmm* or *−hhmm* numeric timezone (that is, the hour and minute offset from UTC). (SU)

%Z The timezone name or abbreviation.

%+ The date and time in *date*(1) format. (TZ) (Not supported in glibc2.)

%% A literal '%' character.

Some conversion specifications can be modified by preceding the conversion specifier character by the **E** or **O** *modifier* to indicate that an alternative format should be used. If the alternative format or specification does not exist for the current locale, the behavior will be as if the unmodified conversion specification were used. (SU) The Single UNIX Specification mentions **%Ec**, **%EC**, **%Ex**, **%EX**, **%Ey**, **%EY**, **%Od**, **%Oe**, **%OH**, **%OI**, **%Om**, **%OM**, **%OS**, **%Ou**, **%OU**, **%OV**, **%Ow**, **%OW**, **%Oy**, where the effect of the **O** modifier is to use alternative numeric symbols (say, roman numerals), and that of the **E** modifier is to use a locale-dependent alternative representation. The rules governing date representation with the **E** modifier can be obtained by supplying **ERA** as an argument to a *nl_langinfo*(3). One example of such alternative forms is the Japanese era calendar scheme in the **ja_JP** glibc locale.

strftime_l() is equivalent to **strftime**(), except it uses the specified *locale* instead of the current locale. The behaviour is undefined if *locale* is invalid or **LC_GLOBAL_LOCALE**.

RETURN VALUE

Provided that the result string, including the terminating null byte, does not exceed *max* bytes, **strftime**() returns the number of bytes (excluding the terminating null byte) placed in the array *s*. If the length of the result string (including the terminating null byte) would exceed *max* bytes, then **strftime**() returns 0, and the contents of the array are undefined.

Note that the return value 0 does not necessarily indicate an error. For example, in many locales **%p** yields an empty string. An empty *format* string will likewise yield an empty string.

ENVIRONMENT

The environment variables **TZ** and **LC_TIME** are used.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strftime(), **strftime_l**()	Thread safety	MT-Safe env locale

STANDARDS

strftime()
C11, POSIX.1-2008.

strftime_l()
POSIX.1-2008.

HISTORY

strftime()
SVr4, C89.

strftime_l()
POSIX.1-2008.

There are strict inclusions between the set of conversions given in ANSI C (unmarked), those given in the Single UNIX Specification (marked SU), those given in Olson's timezone package (marked TZ), and those given in glibc (marked GNU), except that **%+** is not supported in glibc2. On the other hand glibc2 has several more extensions. POSIX.1 only refers to ANSI C; POSIX.2 describes under *date*(1) several extensions that could apply to **strftime**() as well. The **%F** conversion is in C99 and POSIX.1-2001.

In SUSv2, the **%S** specifier allowed a range of 00 to 61, to allow for the theoretical possibility of a minute that included a double leap second (there never has been such a minute).

NOTES

ISO 8601 week dates

%G, **%g**, and **%V** yield values calculated from the week-based year defined by the ISO 8601 standard. In this system, weeks start on a Monday, and are numbered from 01, for the first week, up to 52 or 53, for the last week. Week 1 is the first week where four or more days fall within the new year (or, synonymously, week 01 is: the first week of the year that contains a Thursday; or, the week that has 4 January in it). When three or fewer days of the first calendar week of the new year fall within that year, then the ISO 8601 week-based system counts those days as part of week 52 or 53 of the preceding year. For example, 1 January 2010 is a Friday, meaning that just three days of that calendar week fall in 2010. Thus, the ISO 8601 week-based system considers these days to be part of week 53 (**%V**) of the year 2009 (**%G**); week 01 of ISO 8601 year 2010 starts on Monday, 4 January 2010. Similarly, the first two days of January 2011 are considered to be part of week 52 of the year 2010.

glibc notes

glibc provides some extensions for conversion specifications. (These extensions are not specified in POSIX.1-2001, but a few other systems provide similar features.) Between the '%' character and the conversion specifier character, an optional *flag* and field *width* may be specified. (These precede the **E** or **O** modifiers, if present.)

The following flag characters are permitted:

_ (underscore) Pad a numeric result string with spaces.

- (dash) Do not pad a numeric result string.

0 Pad a numeric result string with zeros even if the conversion specifier character uses space-padding by default.

^ Convert alphabetic characters in result string to uppercase.

Swap the case of the result string. (This flag works only with certain conversion specifier characters, and of these, it is only really useful with **%Z**.)

An optional decimal width specifier may follow the (possibly absent) flag. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width.

BUGS

If the output string would exceed *max* bytes, *errno* is *not* set. This makes it impossible to distinguish this error case from cases where the *format* string legitimately produces a zero-length output string. POSIX.1-2001 does *not* specify any *errno* settings for **strftime**().

Some buggy versions of *gcc*(1) complain about the use of **%c**: *warning: `%c' yields only last 2 digits of year in some locales*. Of course programmers are encouraged to use **%c**, as it gives the preferred date and time representation. One meets all kinds of strange obfuscations to circumvent this *gcc*(1) problem. A relatively clean one is to add an intermediate function

```
size_t
my_strftime(char *s, size_t max, const char *fmt,
            const struct tm *tm)
{
    return strftime(s, max, fmt, tm);
```

```
}
```

Nowadays, *gcc*(1) provides the *−Wno−format−y2k* option to prevent the warning, so that the above workaround is no longer required.

EXAMPLES

RFC 2822-compliant date format (with an English locale for %a and %b)

```
"%a, %d %b %Y %T %z"
```

RFC 822-compliant date format (with an English locale for %a and %b)

```
"%a, %d %b %y %T %z"
```

Example program

The program below can be used to experiment with **strftime**().

Some examples of the result string produced by the glibc implementation of **strftime**() are as follows:

```
$ ./a.out '%m'
Result string is "11"
$ ./a.out '%5m'
Result string is "00011"
$ ./a.out '%_5m'
Result string is "   11"
```

Program source

```
#include <stdio.h>
#include <stdlib.h>
#include <time.h>

int
main(int argc, char *argv[])
{
    char outstr[200];
    time_t t;
    struct tm *tmp;

    t = time(NULL);
    tmp = localtime(&t);
    if (tmp == NULL) {
        perror("localtime");
        exit(EXIT_FAILURE);
    }

    if (strftime(outstr, sizeof(outstr), argv[1], tmp) == 0) {
        fprintf(stderr, "strftime returned 0");
        exit(EXIT_FAILURE);
    }

    printf("Result string is \"%s\"\n", outstr);
    exit(EXIT_SUCCESS);
}
```

NAME

stpcpy, strcasecmp, strcat, strchr, strcmp, strcoll, strcpy, strcspn, strdup, strfry, strlen, strncat, strncmp, strncpy, strncasecmp, strpbrk, strrchr, strsep, strspn, strstr, strtok, strxfrm, index, rindex − string operations

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <strings.h>

int strcasecmp(const char ****s1*, const char ****s2***);**
Compare the strings *s1* and *s2* ignoring case.

int strncasecmp(const char *s1***[.***n***], const char** *s2***[.***n***], size_t** *n***);**
Compare the first *n* bytes of the strings *s1* and *s2* ignoring case.

char *index(const char ****s*, int** *c***);**
Identical to *strchr*(3).

char *rindex(const char ****s*, int** *c***);**
Identical to *strrchr*(3).

#include <string.h>

char *stpcpy(char *restrict *dest***, const char *restrict** *src***);**
Copy a string from *src* to *dest*, returning a pointer to the end of the resulting string at *dest*.

char *strcat(char *restrict *dest***, const char *restrict** *src***);**
Append the string *src* to the string *dest*, returning a pointer *dest*.

char *strchr(const char ****s*, int** *c***);**
Return a pointer to the first occurrence of the character *c* in the string *s*.

int strcmp(const char ****s1*, const char ****s2***);**
Compare the strings *s1* with *s2*.

int strcoll(const char ****s1*, const char ****s2***);**
Compare the strings *s1* with *s2* using the current locale.

char *strcpy(char *restrict *dest***, const char *restrict** *src***);**
Copy the string *src* to *dest*, returning a pointer to the start of *dest*.

size_t strcspn(const char ****s*, const char ****reject***);**
Calculate the length of the initial segment of the string *s* which does not contain any of bytes in the string *reject*,

char *strdup(const char ****s*);**
Return a duplicate of the string *s* in memory allocated using *malloc*(3).

char *strfry(char ****string*);**
Randomly swap the characters in *string*.

size_t strlen(const char ****s*);**
Return the length of the string *s*.

char *strncat(char *dest***[restrict strlen(.***dest***) + .***n* **+ 1],**
const char *src***[restrict .***n***],**
size_t *n***);**
Append at most *n* bytes from the unterminated string *src* to the string *dest*, returning a pointer to *dest*.

int strncmp(const char *s1***[.***n***], const char** *s2***[.***n***], size_t** *n***);**
Compare at most *n* bytes of the strings *s1* and *s2*.

char *strpbrk(const char ****s*, const char ****accept***);**
Return a pointer to the first occurrence in the string *s* of one of the bytes in the string *accept*.

char *strrchr(const char ****s*, int** *c***);**
Return a pointer to the last occurrence of the character *c* in the string *s*.

char *strsep(char **restrict *stringp***, const char *restrict** *delim***);**
Extract the initial token in *stringp* that is delimited by one of the bytes in *delim*.

size_t strspn(const char * *s***, const char *** *accept***);**
Calculate the length of the starting segment in the string *s* that consists entirely of bytes in *accept*.

char *strstr(const char * *haystack***, const char *** *needle***);**
Find the first occurrence of the substring *needle* in the string *haystack*, returning a pointer to the found substring.

char *strtok(char *restrict *s***, const char *restrict** *delim***);**
Extract tokens from the string *s* that are delimited by one of the bytes in *delim*.

size_t strxfrm(char *dest***[restrict .**n**], const char** *src***[restrict .**n**],**
size_t *n***);**
Transforms *src* to the current locale and copies the first *n* bytes to *dest*.

char *strncpy(char *dest***[restrict .**n**], const char** *src***[restrict .**n**],**
size_t *n***);**
Fill a fixed-size buffer with leading non-null bytes from a source array, padding with null bytes as needed.

DESCRIPTION

The string functions perform operations on null-terminated strings. See the individual man pages for descriptions of each function.

NAME

strlen − calculate the length of a string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

size_t strlen(const char *s);

DESCRIPTION

The **strlen**() function calculates the length of the string pointed to by *s*, excluding the terminating null byte ('\0').

RETURN VALUE

The **strlen**() function returns the number of bytes in the string pointed to by *s*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strlen()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD.

NOTES

In cases where the input buffer may not contain a terminating null byte, *strnlen*(3) should be used instead.

SEE ALSO

string(3), *strnlen*(3), *wcslen*(3), *wcsnlen*(3)

NAME

strncat − append non-null bytes from a source array to a string, and null-terminate the result

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

char *strncat(char *restrict *dst***, const char** *src***[restrict .**_ssize_**],**
size_t *ssize***);**

DESCRIPTION

This function appends at most *ssize* non-null bytes from the array pointed to by *src*, followed by a null character, to the end of the string pointed to by *dst*. *dst* must point to a string contained in a buffer that is large enough, that is, the buffer size must be at least *strlen(dst) + strnlen(src, ssize) + 1*.

An implementation of this function might be:

```
char *
strncat(char *restrict dst, const char *restrict src, size_t ssize)
{
    #define strnul(s)  (s + strlen(s))

    stpcpy(mempcpy(strnul(dst), src, strnlen(src, ssize)), "");
    return dst;
}
```

RETURN VALUE

strncat() returns *dst*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strncat()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD.

CAVEATS

The name of this function is confusing; it has no relation to *strncpy*(3).

If the destination buffer does not already contain a string, or is not large enough, the behavior is undefined. See **_FORTIFY_SOURCE** in *feature_test_macros*(7).

BUGS

This function can be very inefficient. Read about Shlemiel the painter.

EXAMPLES

```
#include <err.h>
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define nitems(arr)  (sizeof((arr)) / sizeof((arr)[0]))

int
main(void)
{
    size_t  n;

    // Null-padded fixed-size character sequences
    char    pre[4] = "pre.";
    char    new_post[50] = ".foo.bar";
```

```
        // Strings
        char    post[] = ".post";
        char    src[] = "some_long_body.post";
        char    *dest;

        n = nitems(pre) + strlen(src) - strlen(post) + nitems(new_post) + 1;
        dest = malloc(sizeof(*dest) * n);
        if (dest == NULL)
            err(EXIT_FAILURE, "malloc()");

        dest[0] = '\0';  // There's no 'cpy' function to this 'cat'.
        strncat(dest, pre, nitems(pre));
        strncat(dest, src, strlen(src) - strlen(post));
        strncat(dest, new_post, nitems(new_post));

        puts(dest);  // "pre.some_long_body.foo.bar"
        free(dest);
        exit(EXIT_SUCCESS);
    }
```

NAME

strnlen − determine the length of a fixed-size string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

size_t strnlen(const char *s***[.***maxlen***], size_t** *maxlen***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strnlen():
Since glibc 2.10:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **strnlen**() function returns the number of bytes in the string pointed to by *s*, excluding the terminating null byte ('\0'), but at most *maxlen*. In doing this, **strnlen**() looks only at the first *maxlen* characters in the string pointed to by *s* and never beyond *s[maxlen−1]*.

RETURN VALUE

The **strnlen**() function returns *strlen(s)*, if that is less than *maxlen*, or *maxlen* if there is no null terminating ('\0') among the first *maxlen* characters pointed to by *s*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strpbrk − search a string for any of a set of bytes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

char *strpbrk(const char *s, const char *accept);

DESCRIPTION

The **strpbrk**() function locates the first occurrence in the string *s* of any of the bytes in the string *accept*.

RETURN VALUE

The **strpbrk**() function returns a pointer to the byte in *s* that matches one of the bytes in *accept*, or NULL if no such byte is found.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strpbrk()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

NAME

strptime − convert a string representation of time to a time tm structure

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _XOPEN_SOURCE       /* See feature_test_macros(7) */
#include <time.h>

char *strptime(const char *restrict s, const char *restrict format,
               struct tm *restrict tm);
```

DESCRIPTION

The **strptime**() function is the converse of *strftime*(3); it converts the character string pointed to by *s* to values which are stored in the "broken-down time" structure pointed to by *tm*, using the format specified by *format*.

The broken-down time structure *tm* is described in *tm*(3type).

The *format* argument is a character string that consists of field descriptors and text characters, reminiscent of *scanf*(3). Each field descriptor consists of a **%** character followed by another character that specifies the replacement for the field descriptor. All other characters in the *format* string must have a matching character in the input string, except for whitespace, which matches zero or more whitespace characters in the input string. There should be whitespace or other alphanumeric characters between any two field descriptors.

The **strptime**() function processes the input string from left to right. Each of the three possible input elements (whitespace, literal, or format) are handled one after the other. If the input cannot be matched to the format string, the function stops. The remainder of the format and input strings are not processed.

The supported input field descriptors are listed below. In case a text string (such as the name of a day of the week or a month name) is to be matched, the comparison is case insensitive. In case a number is to be matched, leading zeros are permitted but not required.

%% The **%** character.

%a or **%A**
The name of the day of the week according to the current locale, in abbreviated form or the full name.

%b or **%B** or **%h**
The month name according to the current locale, in abbreviated form or the full name.

%c The date and time representation for the current locale.

%C The century number (0–99).

%d or **%e**
The day of month (1–31).

%D Equivalent to **%m/%d/%y**. (This is the American style date, very confusing to non-Americans, especially since **%d/%m/%y** is widely used in Europe. The ISO 8601 standard format is **%Y-%m-%d**.)

%H The hour (0–23).

%I The hour on a 12-hour clock (1–12).

%j The day number in the year (1–366).

%m The month number (1–12).

%M The minute (0–59).

%n Arbitrary whitespace.

%p The locale’s equivalent of AM or PM. (Note: there may be none.)

%r The 12-hour clock time (using the locale's AM or PM). In the POSIX locale equivalent to **%I:%M:%S %p**. If *t_fmt_ampm* is empty in the **LC_TIME** part of the current locale, then the behavior is undefined.

%R Equivalent to **%H:%M**.

%S The second (0–60; 60 may occur for leap seconds; earlier also 61 was allowed).

%t Arbitrary whitespace.

%T Equivalent to **%H:%M:%S**.

%U The week number with Sunday the first day of the week (0–53). The first Sunday of January is the first day of week 1.

%w The ordinal number of the day of the week (0–6), with Sunday = 0.

%W The week number with Monday the first day of the week (0–53). The first Monday of January is the first day of week 1.

%x The date, using the locale's date format.

%X The time, using the locale's time format.

%y The year within century (0–99). When a century is not otherwise specified, values in the range 69–99 refer to years in the twentieth century (1969–1999); values in the range 00–68 refer to years in the twenty-first century (2000–2068).

%Y The year, including century (for example, 1991).

Some field descriptors can be modified by the E or O modifier characters to indicate that an alternative format or specification should be used. If the alternative format or specification does not exist in the current locale, the unmodified field descriptor is used.

The E modifier specifies that the input string may contain alternative locale-dependent versions of the date and time representation:

%Ec The locale's alternative date and time representation.

%EC The name of the base year (period) in the locale's alternative representation.

%Ex The locale's alternative date representation.

%EX The locale's alternative time representation.

%Ey The offset from **%EC** (year only) in the locale's alternative representation.

%EY The full alternative year representation.

The O modifier specifies that the numerical input may be in an alternative locale-dependent format:

%Od or **%Oe**
The day of the month using the locale's alternative numeric symbols; leading zeros are permitted but not required.

%OH The hour (24-hour clock) using the locale's alternative numeric symbols.

%OI The hour (12-hour clock) using the locale's alternative numeric symbols.

%Om The month using the locale's alternative numeric symbols.

%OM The minutes using the locale's alternative numeric symbols.

%OS The seconds using the locale's alternative numeric symbols.

%OU The week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.

%Ow The ordinal number of the day of the week (Sunday=0), using the locale's alternative numeric symbols.

%OW The week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.

%Oy The year (offset from **%C**) using the locale's alternative numeric symbols.

RETURN VALUE

The return value of the function is a pointer to the first character not processed in this function call. In case the input string contains more characters than required by the format string, the return value points right after the last consumed input character. In case the whole input string is consumed, the return value points to the null byte at the end of the string. If **strptime**() fails to match all of the format string and therefore an error occurred, the function returns NULL.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strptime()	Thread safety	MT-Safe env locale

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SUSv2.

NOTES

In principle, this function does not initialize *tm* but stores only the values specified. This means that *tm* should be initialized before the call. Details differ a bit between different UNIX systems. The glibc implementation does not touch those fields which are not explicitly specified, except that it recomputes the *tm_wday* and *tm_yday* field if any of the year, month, or day elements changed.

The 'y' (year in century) specification is taken to specify a year in the range 1950–2049 by glibc 2.0. It is taken to be a year in 1969–2068 since glibc 2.1.

glibc notes

For reasons of symmetry, glibc tries to support for **strptime**() the same format characters as for *strftime*(3). (In most cases, the corresponding fields are parsed, but no field in *tm* is changed.) This leads to

%F Equivalent to **%Y-%m-%d**, the ISO 8601 date format.

%g The year corresponding to the ISO week number, but without the century (0–99).

%G The year corresponding to the ISO week number. (For example, 1991.)

%u The day of the week as a decimal number (1–7, where Monday = 1).

%V The ISO 8601:1988 week number as a decimal number (1–53). If the week (starting on Monday) containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1.

%z An RFC-822/ISO 8601 standard timezone specification.

%Z The timezone name.

Similarly, because of GNU extensions to *strftime*(3), **%k** is accepted as a synonym for **%H**, and **%l** should be accepted as a synonym for **%I**, and **%P** is accepted as a synonym for **%p**. Finally

%s The number of seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC). Leap seconds are not counted unless leap second support is available.

The glibc implementation does not require whitespace between two field descriptors.

EXAMPLES

The following example demonstrates the use of **strptime**() and *strftime*(3).

```
#define _XOPEN_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <time.h>

int
main(void)
{
    struct tm tm;
```

```
        char buf[255];

        memset(&tm, 0, sizeof(tm));
        strptime("2001-11-12 18:31:01", "%Y-%m-%d %H:%M:%S", &tm);
        strftime(buf, sizeof(buf), "%d %b %Y %H:%M", &tm);
        puts(buf);
        exit(EXIT_SUCCESS);
    }
```

NAME

strsep − extract token from string

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

char *strsep(char **restrict *stringp***, const char *restrict** *delim***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strsep():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

If **stringp* is NULL, the **strsep**() function returns NULL and does nothing else. Otherwise, this function finds the first token in the string **stringp* that is delimited by one of the bytes in the string *delim*. This token is terminated by overwriting the delimiter with a null byte ('\0'), and **stringp* is updated to point past the token. In case no delimiter was found, the token is taken to be the entire string **stringp*, and **stringp* is made NULL.

RETURN VALUE

The **strsep**() function returns a pointer to the token, that is, it returns the original value of **stringp*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strsep()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

4.4BSD.

The **strsep**() function was introduced as a replacement for *strtok*(3), since the latter cannot handle empty fields. However, *strtok*(3) conforms to C89/C99 and hence is more portable.

BUGS

Be cautious when using this function. If you do use it, note that:

- This function modifies its first argument.
- This function cannot be used on constant strings.
- The identity of the delimiting character is lost.

EXAMPLES

The program below is a port of the one found in *strtok*(3), which, however, doesn't discard multiple delimiters or empty tokens:

```
$ ./a.out 'a/bbb///cc;xxx:yyy:' ':;' '/'
1: a/bbb///cc
        --> a
        --> bbb
        -->
        -->
        --> cc
2: xxx
        --> xxx
3: yyy
        --> yyy
4:
        -->
```

Program source

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(int argc, char *argv[])
{
    char *token, *subtoken;

    if (argc != 4) {
        fprintf(stderr, "Usage: %s string delim subdelim\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    for (unsigned int j = 1; (token = strsep(&argv[1], argv[2])); j++) {
        printf("%u: %s\n", j, token);

        while ((subtoken = strsep(&token, argv[3])))
            printf("\t --> %s\n", subtoken);
    }

    exit(EXIT_SUCCESS);
}
```

NAME

strsignal, sigabbrev_np, sigdescr_np, sys_siglist − return string describing signal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strsignal(int sig);
const char *sigdescr_np(int sig);
const char *sigabbrev_np(int sig);

[[deprecated]] extern const char *const sys_siglist[];
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

sigabbrev_np(), **sigdescr_np**():
_GNU_SOURCE

strsignal():
From glibc 2.10 to glibc 2.31:
_POSIX_C_SOURCE >= 200809L
Before glibc 2.10:
_GNU_SOURCE

sys_siglist:
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The **strsignal**() function returns a string describing the signal number passed in the argument *sig*. The string can be used only until the next call to **strsignal**(). The string returned by **strsignal**() is localized according to the **LC_MESSAGES** category in the current locale.

The **sigdescr_np**() function returns a string describing the signal number passed in the argument *sig*. Unlike **strsignal**() this string is not influenced by the current locale.

The **sigabbrev_np**() function returns the abbreviated name of the signal, *sig*. For example, given the value **SIGINT**, it returns the string "INT".

The (deprecated) array *sys_siglist* holds the signal description strings indexed by signal number. The **strsignal**() or the **sigdescr_np**() function should be used instead of this array; see also VERSIONS.

RETURN VALUE

The **strsignal**() function returns the appropriate description string, or an unknown signal message if the signal number is invalid. On some systems (but not on Linux), NULL may instead be returned for an invalid signal number.

The **sigdescr_np**() and **sigabbrev_np**() functions return the appropriate description string. The returned string is statically allocated and valid for the lifetime of the program. These functions return NULL for an invalid signal number.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strspn, strcspn − get length of a prefix substring

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

size_t strspn(const char *_s_, const char *_accept_);
size_t strcspn(const char *_s_, const char *_reject_);

DESCRIPTION

The **strspn**() function calculates the length (in bytes) of the initial segment of *s* which consists entirely of bytes in *accept*.

The **strcspn**() function calculates the length of the initial segment of *s* which consists entirely of bytes not in *reject*.

RETURN VALUE

The **strspn**() function returns the number of bytes in the initial segment of *s* which consist only of bytes from *accept*.

The **strcspn**() function returns the number of bytes in the initial segment of *s* which are not in the string *reject*.

ATTRIBUTES

NAME

strstr, strcasestr − locate a substring

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strstr(const char *haystack, const char *needle);

#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <string.h>

char *strcasestr(const char *haystack, const char *needle);
```

DESCRIPTION

The **strstr**() function finds the first occurrence of the substring *needle* in the string *haystack*. The terminating null bytes ('\0') are not compared.

The **strcasestr**() function is like **strstr**(), but ignores the case of both arguments.

RETURN VALUE

These functions return a pointer to the beginning of the located substring, or NULL if the substring is not found.

If *needle* is the empty string, the return value is always *haystack* itself.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strtod, strtof, strtold − convert ASCII string to floating-point number

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

double strtod(const char *restrict nptr, char **restrict endptr);
float strtof(const char *restrict nptr, char **restrict endptr);
long double strtold(const char *restrict nptr, char **restrict endptr);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strtof(), **strtold**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

The **strtod**(), **strtof**(), and **strtold**() functions convert the initial portion of the string pointed to by *nptr* to *double*, *float*, and *long double* representation, respectively.

The expected form of the (initial portion of the) string is optional leading white space as recognized by *isspace*(3), an optional plus ('+') or minus sign ('−') and then either (i) a decimal number, or (ii) a hexadecimal number, or (iii) an infinity, or (iv) a NAN (not-a-number).

A *decimal number* consists of a nonempty sequence of decimal digits possibly containing a radix character (decimal point, locale-dependent, usually '.'), optionally followed by a decimal exponent. A decimal exponent consists of an 'E' or 'e', followed by an optional plus or minus sign, followed by a nonempty sequence of decimal digits, and indicates multiplication by a power of 10.

A *hexadecimal number* consists of a "0x" or "0X" followed by a nonempty sequence of hexadecimal digits possibly containing a radix character, optionally followed by a binary exponent. A binary exponent consists of a 'P' or 'p', followed by an optional plus or minus sign, followed by a nonempty sequence of decimal digits, and indicates multiplication by a power of 2. At least one of radix character and binary exponent must be present.

An *infinity* is either "INF" or "INFINITY", disregarding case.

A *NAN* is "NAN" (disregarding case) optionally followed by a string, *(n-char-sequence)*, where *n-char-sequence* specifies in an implementation-dependent way the type of NAN (see NOTES).

RETURN VALUE

These functions return the converted value, if any.

If *endptr* is not NULL, a pointer to the character after the last character used in the conversion is stored in the location referenced by *endptr*.

If no conversion is performed, zero is returned and (unless *endptr* is null) the value of *nptr* is stored in the location referenced by *endptr*.

If the correct value would cause overflow, plus or minus **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL** is returned (according to the return type and sign of the value), and **ERANGE** is stored in *errno*.

If the correct value would cause underflow, a value with magnitude no larger than **DBL_MIN**, **FLT_MIN**, or **LDBL_MIN** is returned and **ERANGE** is stored in *errno*.

ERRORS

ERANGE
Overflow or underflow occurred.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strtod(), **strtof**(), **strtold**()	Thread safety	MT-Safe locale

VERSIONS

In the glibc implementation, the *n-char-sequence* that optionally follows "NAN" is interpreted as an integer number (with an optional ’0’ or ’0x’ prefix to select base 8 or 16) that is to be placed in the

mantissa component of the returned value.

STANDARDS

C11, POSIX.1-2008.

HISTORY

strtod()

C89, POSIX.1-2001.

strtof()
strtold()

C99, POSIX.1-2001.

NOTES

Since 0 can legitimately be returned on both success and failure, the calling program should set *errno* to 0 before the call, and then determine if an error occurred by checking whether *errno* has a nonzero value after the call.

EXAMPLES

See the example on the *strtol*(3) manual page; the use of the functions described in this manual page is similar.

NAME

strtoimax, strtoumax − convert string to integer

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <inttypes.h>

intmax_t strtoimax(const char *restrict nptr, char **restrict endptr,
                   int base);
uintmax_t strtoumax(const char *restrict nptr, char **restrict endptr,
                    int base);
```

DESCRIPTION

These functions are just like *strtol*(3) and *strtoul*(3), except that they return a value of type *intmax_t* and *uintmax_t*, respectively.

RETURN VALUE

On success, the converted value is returned. If nothing was found to convert, zero is returned. On overflow or underflow **INTMAX_MAX** or **INTMAX_MIN** or **UINTMAX_MAX** is returned, and *errno* is set to **ERANGE**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

strtok, strtok_r − extract tokens from strings

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <string.h>

char *strtok(char *restrict str, const char *restrict delim);
char *strtok_r(char *restrict str, const char *restrict delim,
        char **restrict saveptr);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strtok_r():
  _POSIX_C_SOURCE
    || /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **strtok**() function breaks a string into a sequence of zero or more nonempty tokens. On the first call to **strtok**(), the string to be parsed should be specified in *str*. In each subsequent call that should parse the same string, *str* must be NULL.

The *delim* argument specifies a set of bytes that delimit the tokens in the parsed string. The caller may specify different strings in *delim* in successive calls that parse the same string.

Each call to **strtok**() returns a pointer to a null-terminated string containing the next token. This string does not include the delimiting byte. If no more tokens are found, **strtok**() returns NULL.

A sequence of calls to **strtok**() that operate on the same string maintains a pointer that determines the point from which to start searching for the next token. The first call to **strtok**() sets this pointer to point to the first byte of the string. The start of the next token is determined by scanning forward for the next nondelimiter byte in *str*. If such a byte is found, it is taken as the start of the next token. If no such byte is found, then there are no more tokens, and **strtok**() returns NULL. (A string that is empty or that contains only delimiters will thus cause **strtok**() to return NULL on the first call.)

The end of each token is found by scanning forward until either the next delimiter byte is found or until the terminating null byte ('\0') is encountered. If a delimiter byte is found, it is overwritten with a null byte to terminate the current token, and **strtok**() saves a pointer to the following byte; that pointer will be used as the starting point when searching for the next token. In this case, **strtok**() returns a pointer to the start of the found token.

From the above description, it follows that a sequence of two or more contiguous delimiter bytes in the parsed string is considered to be a single delimiter, and that delimiter bytes at the start or end of the string are ignored. Put another way: the tokens returned by **strtok**() are always nonempty strings. Thus, for example, given the string "*aaa;;bbb,*", successive calls to **strtok**() that specify the delimiter string "*;*," would return the strings "*aaa*" and "*bbb*", and then a null pointer.

The **strtok_r**() function is a reentrant version of **strtok**(). The *saveptr* argument is a pointer to a *char* * variable that is used internally by **strtok_r**() in order to maintain context between successive calls that parse the same string.

On the first call to **strtok_r**(), *str* should point to the string to be parsed, and the value of **saveptr* is ignored (but see NOTES). In subsequent calls, *str* should be NULL, and *saveptr* (and the buffer that it points to) should be unchanged since the previous call.

Different strings may be parsed concurrently using sequences of calls to **strtok_r**() that specify different *saveptr* arguments.

RETURN VALUE

The **strtok**() and **strtok_r**() functions return a pointer to the next token, or NULL if there are no more tokens.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strtok()	Thread safety	MT-Unsafe race:strtok
strtok_r()	Thread safety	MT-Safe

VERSIONS

On some implementations, **saveptr* is required to be NULL on the first call to **strtok_r**() that is being used to parse *str*.

STANDARDS

strtok()
: C11, POSIX.1-2008.

strtok_r()
: POSIX.1-2008.

HISTORY

strtok()
: POSIX.1-2001, C89, SVr4, 4.3BSD.

strtok_r()
: POSIX.1-2001.

BUGS

Be cautious when using these functions. If you do use them, note that:

- These functions modify their first argument.
- These functions cannot be used on constant strings.
- The identity of the delimiting byte is lost.
- The **strtok**() function uses a static buffer while parsing, so it's not thread safe. Use **strtok_r**() if this matters to you.

EXAMPLES

The program below uses nested loops that employ **strtok_r**() to break a string into a two-level hierarchy of tokens. The first command-line argument specifies the string to be parsed. The second argument specifies the delimiter byte(s) to be used to separate that string into "major" tokens. The third argument specifies the delimiter byte(s) to be used to separate the "major" tokens into subtokens.

An example of the output produced by this program is the following:

```
$ ./a.out 'a/bbb///cc;xxx:yyy:' ':;' '/'
1: a/bbb///cc
        --> a
        --> bbb
        --> cc
2: xxx
        --> xxx
3: yyy
        --> yyy
```

Program source

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(int argc, char *argv[])
{
    char *str1, *str2, *token, *subtoken;
    char *saveptr1, *saveptr2;
    int j;

    if (argc != 4) {
        fprintf(stderr, "Usage: %s string delim subdelim\n",
```

```
                argv[0]);
        exit(EXIT_FAILURE);
    }

    for (j = 1, str1 = argv[1]; ; j++, str1 = NULL) {
        token = strtok_r(str1, argv[2], &saveptr1);
        if (token == NULL)
            break;
        printf("%d: %s\n", j, token);

        for (str2 = token; ; str2 = NULL) {
            subtoken = strtok_r(str2, argv[3], &saveptr2);
            if (subtoken == NULL)
                break;
            printf("\t --> %s\n", subtoken);
        }
    }

    exit(EXIT_SUCCESS);
}
```

Another example program using **strtok**() can be found in *getaddrinfo_a*(3).

NAME

strtol, strtoll, strtoq − convert a string to a long integer

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

long strtol(const char *restrict nptr,
        char **restrict endptr, int base);
long long strtoll(const char *restrict nptr,
        char **restrict endptr, int base);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strtoll():
_ISOC99_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

DESCRIPTION

The **strtol**() function converts the initial part of the string in *nptr* to a long integer value according to the given *base*, which must be between 2 and 36 inclusive, or be the special value 0.

The string may begin with an arbitrary amount of white space (as determined by *isspace*(3)) followed by a single optional '+' or '−' sign. If *base* is zero or 16, the string may then include a "0x" or "0X" prefix, and the number will be read in base 16; otherwise, a zero *base* is taken as 10 (decimal) unless the next character is '0', in which case it is taken as 8 (octal).

The remainder of the string is converted to a *long* value in the obvious manner, stopping at the first character which is not a valid digit in the given base. (In bases above 10, the letter 'A' in either uppercase or lowercase represents 10, 'B' represents 11, and so forth, with 'Z' representing 35.)

If *endptr* is not NULL, and the *base* is supported, **strtol**() stores the address of the first invalid character in **endptr*. If there were no digits at all, **strtol**() stores the original value of *nptr* in **endptr* (and returns 0). In particular, if **nptr* is not '\0' but ***endptr* is '\0' on return, the entire string is valid.

The **strtoll**() function works just like the **strtol**() function but returns a *long long* integer value.

RETURN VALUE

The **strtol**() function returns the result of the conversion, unless the value would underflow or overflow. If an underflow occurs, **strtol**() returns **LONG_MIN**. If an overflow occurs, **strtol**() returns **LONG_MAX**. In both cases, *errno* is set to **ERANGE**. Precisely the same holds for **strtoll**() (with **LLONG_MIN** and **LLONG_MAX** instead of **LONG_MIN** and **LONG_MAX**).

ERRORS

This function does not modify *errno* on success.

EINVAL
(not in C99) The given *base* contains an unsupported value.

ERANGE
The resulting value was out of range.

The implementation may also set *errno* to **EINVAL** in case no conversion was performed (no digits seen, and 0 returned).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strtol(), **strtoll**(), **strtoq**()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

strtol() POSIX.1-2001, C89, SVr4, 4.3BSD.

strtoll()
POSIX.1-2001, C99.

NOTES

Since **strtol**() can legitimately return 0, **LONG_MAX**, or **LONG_MIN** (**LLONG_MAX** or **LLONG_MIN** for *strtoll*()) on both success and failure, the calling program should set *errno* to 0 before the call, and then determine if an error occurred by checking whether *errno* == *ERANGE* after the call.

According to POSIX.1, in locales other than "C" and "POSIX", these functions may accept other, implementation-defined numeric strings.

BSD also has

```
quad_t strtoq(const char *nptr, char **endptr, int base);
```

with completely analogous definition. Depending on the wordsize of the current architecture, this may be equivalent to **strtoll**() or to **strtol**().

CAVEATS

If the *base* needs to be tested, it should be tested in a call where the string is known to succeed. Otherwise, it's impossible to portably differentiate the errors.

```
errno = 0;
strtol("0", NULL, base);
if (errno == EINVAL)
    goto unsupported_base;
```

EXAMPLES

The program shown below demonstrates the use of **strtol**(). The first command-line argument specifies a string from which **strtol**() should parse a number. The second (optional) argument specifies the base to be used for the conversion. (This argument is converted to numeric form using *atoi*(3), a function that performs no error checking and has a simpler interface than *strtol*().) Some examples of the results produced by this program are the following:

```
$ ./a.out 123
strtol() returned 123
$ ./a.out '    123'
strtol() returned 123
$ ./a.out 123abc
strtol() returned 123
Further characters after number: "abc"
$ ./a.out 123abc 55
strtol: Invalid argument
$ ./a.out ''
No digits were found
$ ./a.out 4000000000
strtol: Numerical result out of range
```

Program source

```
#include <errno.h>
#include <stdio.h>
#include <stdlib.h>

int
main(int argc, char *argv[])
{
    int base;
    char *endptr, *str;
    long val;

    if (argc < 2) {
        fprintf(stderr, "Usage: %s str [base]\n", argv[0]);
        exit(EXIT_FAILURE);
```

```
        }

        str = argv[1];
        base = (argc > 2) ? atoi(argv[2]) : 0;

        errno = 0;    /* To distinguish success/failure after call */
        strtol("0", NULL, base);
        if (errno == EINVAL) {
            perror("strtol");
            exit(EXIT_FAILURE);
        }

        errno = 0;    /* To distinguish success/failure after call */
        val = strtol(str, &endptr, base);

        /* Check for various possible errors. */

        if (errno == ERANGE) {
            perror("strtol");
            exit(EXIT_FAILURE);
        }

        if (endptr == str) {
            fprintf(stderr, "No digits were found\n");
            exit(EXIT_FAILURE);
        }

        /* If we got here, strtol() successfully parsed a number. */

        printf("strtol() returned %ld\n", val);

        if (*endptr != '\0')        /* Not necessarily an error... */
            printf("Further characters after number: \"%s\"\n", endptr);

        exit(EXIT_SUCCESS);
    }
```

NAME

strtoul, strtoull, strtouq − convert a string to an unsigned long integer

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdlib.h>

unsigned long strtoul(const char *restrict nptr,
                      char **restrict endptr, int base);
unsigned long long strtoull(const char *restrict nptr,
                      char **restrict endptr, int base);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

strtoull():
_ISOC99_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

DESCRIPTION

The **strtoul**() function converts the initial part of the string in *nptr* to an *unsigned long* value according to the given *base*, which must be between 2 and 36 inclusive, or be the special value 0.

The string may begin with an arbitrary amount of white space (as determined by *isspace*(3)) followed by a single optional '+' or '−' sign. If *base* is zero or 16, the string may then include a "0x" prefix, and the number will be read in base 16; otherwise, a zero *base* is taken as 10 (decimal) unless the next character is '0', in which case it is taken as 8 (octal).

The remainder of the string is converted to an *unsigned long* value in the obvious manner, stopping at the first character which is not a valid digit in the given base. (In bases above 10, the letter 'A' in either uppercase or lowercase represents 10, 'B' represents 11, and so forth, with 'Z' representing 35.)

If *endptr* is not NULL, and the *base* is supported, **strtoul**() stores the address of the first invalid character in **endptr*. If there were no digits at all, **strtoul**() stores the original value of *nptr* in **endptr* (and returns 0). In particular, if **nptr* is not '\0' but ***endptr* is '\0' on return, the entire string is valid.

The **strtoull**() function works just like the **strtoul**() function but returns an *unsigned long long* value.

RETURN VALUE

The **strtoul**() function returns either the result of the conversion or, if there was a leading minus sign, the negation of the result of the conversion represented as an unsigned value, unless the original (non-negated) value would overflow; in the latter case, **strtoul**() returns **ULONG_MAX** and sets *errno* to **ERANGE**. Precisely the same holds for **strtoull**() (with **ULLONG_MAX** instead of **ULONG_MAX**).

ERRORS

This function does not modify *errno* on success.

EINVAL
(not in C99) The given *base* contains an unsupported value.

ERANGE
The resulting value was out of range.

The implementation may also set *errno* to **EINVAL** in case no conversion was performed (no digits seen, and 0 returned).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strtoul(), **strtoull**(), **strtouq**()	Thread safety	MT-Safe locale

STANDARDS

C11, POSIX.1-2008.

HISTORY

strtoul()
POSIX.1-2001, C89, SVr4.

strtoull()
POSIX.1-2001, C99.

NOTES

Since **strtoul**() can legitimately return 0 or **ULONG_MAX** (**ULLONG_MAX** for *strtoull*()) on both success and failure, the calling program should set *errno* to 0 before the call, and then determine if an error occurred by checking whether *errno* has a nonzero value after the call.

In locales other than the "C" locale, other strings may be accepted. (For example, the thousands separator of the current locale may be supported.)

BSD also has

```
u_quad_t strtouq(const char *nptr, char **endptr, int base);
```

with completely analogous definition. Depending on the wordsize of the current architecture, this may be equivalent to **strtoull**() or to **strtoul**().

Negative values are considered valid input and are silently converted to the equivalent *unsigned long* value.

EXAMPLES

See the example on the *strtol*(3) manual page; the use of the functions described in this manual page is similar.

NAME

strverscmp − compare two version strings

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#define _GNU_SOURCE /* See feature_test_macros(7) */
#include <string.h>

int strverscmp(const char *_s1_, const char *_s2_);

DESCRIPTION

Often one has files *jan1*, *jan2*, ..., *jan9*, *jan10*, ... and it feels wrong when *ls*(1) orders them *jan1*, *jan10*, ..., *jan2*, ..., *jan9*. In order to rectify this, GNU introduced the *−v* option to *ls*(1), which is implemented using *versionsort*(3), which again uses **strverscmp**().

Thus, the task of **strverscmp**() is to compare two strings and find the "right" order, while *strcmp*(3) finds only the lexicographic order. This function does not use the locale category **LC_COLLATE**, so is meant mostly for situations where the strings are expected to be in ASCII.

What this function does is the following. If both strings are equal, return 0. Otherwise, find the position between two bytes with the property that before it both strings are equal, while directly after it there is a difference. Find the largest consecutive digit strings containing (or starting at, or ending at) this position. If one or both of these is empty, then return what *strcmp*(3) would have returned (numerical ordering of byte values). Otherwise, compare both digit strings numerically, where digit strings with one or more leading zeros are interpreted as if they have a decimal point in front (so that in particular digit strings with more leading zeros come before digit strings with fewer leading zeros). Thus, the ordering is *000*, *00*, *01*, *010*, *09*, *0*, *1*, *9*, *10*.

RETURN VALUE

The **strverscmp**() function returns an integer less than, equal to, or greater than zero if *s1* is found, respectively, to be earlier than, equal to, or later than *s2*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strverscmp()	Thread safety	MT-Safe

STANDARDS

GNU.

EXAMPLES

The program below can be used to demonstrate the behavior of **strverscmp**(). It uses **strverscmp**() to compare the two strings given as its command-line arguments. An example of its use is the following:

```
$ ./a.out jan1 jan10
jan1 < jan10
```

Program source

```
#define _GNU_SOURCE
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int
main(int argc, char *argv[])
{
    int res;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <string1> <string2>\n", argv[0]);
        exit(EXIT_FAILURE);
    }
```

```
        res = strverscmp(argv[1], argv[2]);

        printf("%s %s %s\n", argv[1],
               (res < 0) ? "<" : (res == 0) ? "==" : ">", argv[2]);

        exit(EXIT_SUCCESS);
    }
```

NAME

strxfrm − string transformation

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <string.h>

size_t strxfrm(char *dest***[restrict .***n***], const char** *src***[restrict .***n***],**
size_t *n***);**

DESCRIPTION

The **strxfrm**() function transforms the *src* string into a form such that the result of *strcmp*(3) on two strings that have been transformed with **strxfrm**() is the same as the result of *strcoll*(3) on the two strings before their transformation. The first *n* bytes of the transformed string are placed in *dest*. The transformation is based on the program's current locale for category **LC_COLLATE**. (See *setlocale*(3)).

RETURN VALUE

The **strxfrm**() function returns the number of bytes required to store the transformed string in *dest* excluding the terminating null byte ('\0'). If the value returned is *n* or more, the contents of *dest* are indeterminate.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
strxfrm()	Thread safety	MT-Safe locale

NAME

swab − swap adjacent bytes

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _XOPEN_SOURCE       /* See feature_test_macros(7) */
#include <unistd.h>

void swab(const void *from[restrict .n], void *to[restrict .n],
          ssize_t n);
```

DESCRIPTION

The **swab**() function copies *n* bytes from the array pointed to by *from* to the array pointed to by *to*, exchanging adjacent even and odd bytes. This function is used to exchange data between machines that have different low/high byte ordering.

This function does nothing when *n* is negative. When *n* is positive and odd, it handles *n−1* bytes as above, and does something unspecified with the last byte. (In other words, *n* should be even.)

RETURN VALUE

The **swab**() function returns no value.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

sysconf − get configuration information at run time

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

long sysconf(int *name***);**

DESCRIPTION

POSIX allows an application to test at compile or run time whether certain options are supported, or what the value is of certain configurable constants or limits.

At compile time this is done by including <*unistd.h*> and/or <*limits.h*> and testing the value of certain macros.

At run time, one can ask for numerical values using the present function **sysconf**(). One can ask for numerical values that may depend on the filesystem in which a file resides using *fpathconf*(3) and *pathconf*(3). One can ask for string values using *confstr*(3).

The values obtained from these functions are system configuration constants. They do not change during the lifetime of a process.

For options, typically, there is a constant **_POSIX_FOO** that may be defined in <*unistd.h*>. If it is undefined, one should ask at run time. If it is defined to −1, then the option is not supported. If it is defined to 0, then relevant functions and headers exist, but one has to ask at run time what degree of support is available. If it is defined to a value other than −1 or 0, then the option is supported. Usually the value (such as 200112L) indicates the year and month of the POSIX revision describing the option. glibc uses the value 1 to indicate support as long as the POSIX revision has not been published yet. The **sysconf**() argument will be **_SC_FOO**. For a list of options, see *posixoptions*(7).

For variables or limits, typically, there is a constant **_FOO**, maybe defined in <*limits.h*>, or **_POSIX_FOO**, maybe defined in <*unistd.h*>. The constant will not be defined if the limit is unspecified. If the constant is defined, it gives a guaranteed value, and a greater value might actually be supported. If an application wants to take advantage of values which may change between systems, a call to **sysconf**() can be made. The **sysconf**() argument will be **_SC_FOO**.

POSIX.1 variables

We give the name of the variable, the name of the **sysconf**() argument used to inquire about its value, and a short description.

First, the POSIX.1 compatible values.

ARG_MAX - _SC_ARG_MAX
: The maximum length of the arguments to the *exec*(3) family of functions. Must not be less than **_POSIX_ARG_MAX** (4096).

CHILD_MAX - _SC_CHILD_MAX
: The maximum number of simultaneous processes per user ID. Must not be less than **_POSIX_CHILD_MAX** (25).

HOST_NAME_MAX - _SC_HOST_NAME_MAX
: Maximum length of a hostname, not including the terminating null byte, as returned by *gethostname*(2). Must not be less than **_POSIX_HOST_NAME_MAX** (255).

LOGIN_NAME_MAX - _SC_LOGIN_NAME_MAX
: Maximum length of a login name, including the terminating null byte. Must not be less than **_POSIX_LOGIN_NAME_MAX** (9).

NGROUPS_MAX - _SC_NGROUPS_MAX
: Maximum number of supplementary group IDs.

clock ticks - **_SC_CLK_TCK**
: The number of clock ticks per second. The corresponding variable is obsolete. It was of course called **CLK_TCK**. (Note: the macro **CLOCKS_PER_SEC** does not give information: it must equal 1000000.)

OPEN_MAX - **_SC_OPEN_MAX**
The maximum number of files that a process can have open at any time. Must not be less than **_POSIX_OPEN_MAX** (20).

PAGESIZE - **_SC_PAGESIZE**
Size of a page in bytes. Must not be less than 1.

PAGE_SIZE - **_SC_PAGE_SIZE**
A synonym for **PAGESIZE**/**_SC_PAGESIZE**. (Both **PAGESIZE** and **PAGE_SIZE** are specified in POSIX.)

RE_DUP_MAX - **_SC_RE_DUP_MAX**
The number of repeated occurrences of a BRE permitted by *regexec*(3) and *regcomp*(3). Must not be less than **_POSIX2_RE_DUP_MAX** (255).

STREAM_MAX - **_SC_STREAM_MAX**
The maximum number of streams that a process can have open at any time. If defined, it has the same value as the standard C macro **FOPEN_MAX**. Must not be less than **_POSIX_STREAM_MAX** (8).

SYMLOOP_MAX - **_SC_SYMLOOP_MAX**
The maximum number of symbolic links seen in a pathname before resolution returns **ELOOP**. Must not be less than **_POSIX_SYMLOOP_MAX** (8).

TTY_NAME_MAX - **_SC_TTY_NAME_MAX**
The maximum length of terminal device name, including the terminating null byte. Must not be less than **_POSIX_TTY_NAME_MAX** (9).

TZNAME_MAX - **_SC_TZNAME_MAX**
The maximum number of bytes in a timezone name. Must not be less than **_POSIX_TZNAME_MAX** (6).

_POSIX_VERSION - **_SC_VERSION**
indicates the year and month the POSIX.1 standard was approved in the format **YYYYMML**; the value **199009L** indicates the Sept. 1990 revision.

POSIX.2 variables
Next, the POSIX.2 values, giving limits for utilities.

BC_BASE_MAX - **_SC_BC_BASE_MAX**
indicates the maximum *obase* value accepted by the *bc*(1) utility.

BC_DIM_MAX - **_SC_BC_DIM_MAX**
indicates the maximum value of elements permitted in an array by *bc*(1)

BC_SCALE_MAX - **_SC_BC_SCALE_MAX**
indicates the maximum *scale* value allowed by *bc*(1)

BC_STRING_MAX - **_SC_BC_STRING_MAX**
indicates the maximum length of a string accepted by *bc*(1)

COLL_WEIGHTS_MAX - **_SC_COLL_WEIGHTS_MAX**
indicates the maximum numbers of weights that can be assigned to an entry of the **LC_COLLATE order** keyword in the locale definition file.

EXPR_NEST_MAX - **_SC_EXPR_NEST_MAX**
is the maximum number of expressions which can be nested within parentheses by *expr*(1)

LINE_MAX - **_SC_LINE_MAX**
The maximum length of a utility's input line, either from standard input or from a file. This includes space for a trailing newline.

RE_DUP_MAX - **_SC_RE_DUP_MAX**
The maximum number of repeated occurrences of a regular expression when the interval notation **\{m,n\}** is used.

POSIX2_VERSION - **_SC_2_VERSION**
indicates the version of the POSIX.2 standard in the format of YYYYMML.

POSIX2_C_DEV - _SC_2_C_DEV
indicates whether the POSIX.2 C language development facilities are supported.

POSIX2_FORT_DEV - _SC_2_FORT_DEV
indicates whether the POSIX.2 FORTRAN development utilities are supported.

POSIX2_FORT_RUN - _SC_2_FORT_RUN
indicates whether the POSIX.2 FORTRAN run-time utilities are supported.

_POSIX2_LOCALEDEF - _SC_2_LOCALEDEF
indicates whether the POSIX.2 creation of locales via *localedef*(1) is supported.

POSIX2_SW_DEV - _SC_2_SW_DEV
indicates whether the POSIX.2 software development utilities option is supported.

These values also exist, but may not be standard.

- **_SC_PHYS_PAGES**
The number of pages of physical memory. Note that it is possible for the product of this value and the value of **_SC_PAGESIZE** to overflow.

- **_SC_AVPHYS_PAGES**
The number of currently available pages of physical memory.

- **_SC_NPROCESSORS_CONF**
The number of processors configured. See also *get_nprocs_conf*(3).

- **_SC_NPROCESSORS_ONLN**
The number of processors currently online (available). See also *get_nprocs_conf*(3).

RETURN VALUE

The return value of **sysconf**() is one of the following:

- On error, −1 is returned and *errno* is set to indicate the error (for example, **EINVAL**, indicating that *name* is invalid).
- If *name* corresponds to a maximum or minimum limit, and that limit is indeterminate, −1 is returned and *errno* is not changed. (To distinguish an indeterminate limit from an error, set *errno* to zero before the call, and then check whether *errno* is nonzero when −1 is returned.)
- If *name* corresponds to an option, a positive value is returned if the option is supported, and −1 is returned if the option is not supported.
- Otherwise, the current value of the option or limit is returned. This value will not be more restrictive than the corresponding value that was described to the application in <*unistd.h*> or <*limits.h*> when the application was compiled.

ERRORS

EINVAL
name is invalid.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sysconf()	Thread safety	MT-Safe env

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001.

BUGS

It is difficult to use **ARG_MAX** because it is not specified how much of the argument space for *exec*(3) is consumed by the user's environment variables.

Some returned values may be huge; they are not suitable for allocating memory.

NAME

closelog, openlog, syslog, vsyslog − send messages to the system logger

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <syslog.h>

void openlog(const char *ident, int option, int facility);
void syslog(int priority, const char * format, ...);
void closelog(void);

void vsyslog(int priority, const char * format, va_list ap);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

vsyslog():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

openlog()

openlog() opens a connection to the system logger for a program.

The string pointed to by *ident* is prepended to every message, and is typically set to the program name. If *ident* is NULL, the program name is used. (POSIX.1-2008 does not specify the behavior when *ident* is NULL.)

The *option* argument specifies flags which control the operation of **openlog**() and subsequent calls to **syslog**(). The *facility* argument establishes a default to be used if none is specified in subsequent calls to **syslog**(). The values that may be specified for *option* and *facility* are described below.

The use of **openlog**() is optional; it will automatically be called by **syslog**() if necessary, in which case *ident* will default to NULL.

syslog() and vsyslog()

syslog() generates a log message, which will be distributed by *syslogd*(8)

The *priority* argument is formed by ORing together a *facility* value and a *level* value (described below). If no *facility* value is ORed into *priority*, then the default value set by **openlog**() is used, or, if there was no preceding **openlog**() call, a default of **LOG_USER** is employed.

The remaining arguments are a *format*, as in *printf*(3), and any arguments required by the *format*, except that the two-character sequence **%m** will be replaced by the error message string *strerror*(*errno*). The format string need not include a terminating newline character.

The function **vsyslog**() performs the same task as **syslog**() with the difference that it takes a set of arguments which have been obtained using the *stdarg*(3) variable argument list macros.

closelog()

closelog() closes the file descriptor being used to write to the system logger. The use of **closelog**() is optional.

Values for *option*

The *option* argument to **openlog**() is a bit mask constructed by ORing together any of the following values:

LOG_CONS Write directly to the system console if there is an error while sending to the system logger.

LOG_NDELAY Open the connection immediately (normally, the connection is opened when the first message is logged). This may be useful, for example, if a subsequent *chroot*(2) would make the pathname used internally by the logging facility unreachable.

LOG_NOWAIT Don't wait for child processes that may have been created while logging the message. (The GNU C library does not create a child process, so this option has no effect on Linux.)

LOG_ODELAY The converse of **LOG_NDELAY**; opening of the connection is delayed until **syslog**() is called. (This is the default, and need not be specified.)

LOG_PERROR (Not in POSIX.1-2001 or POSIX.1-2008.) Also log the message to *stderr*.

LOG_PID Include the caller's PID with each message.

Values for *facility*

The *facility* argument is used to specify what type of program is logging the message. This lets the configuration file specify that messages from different facilities will be handled differently.

LOG_AUTH security/authorization messages

LOG_AUTHPRIV
security/authorization messages (private)

LOG_CRON clock daemon (**cron** and **at**)

LOG_DAEMON
system daemons without separate facility value

LOG_FTP ftp daemon

LOG_KERN kernel messages (these can't be generated from user processes)

LOG_LOCAL0 through **LOG_LOCAL7**
reserved for local use

LOG_LPR line printer subsystem

LOG_MAIL mail subsystem

LOG_NEWS USENET news subsystem

LOG_SYSLOG messages generated internally by *syslogd*(8)

LOG_USER (default)
generic user-level messages

LOG_UUCP UUCP subsystem

Values for *level*

This determines the importance of the message. The levels are, in order of decreasing importance:

LOG_EMERG system is unusable

LOG_ALERT action must be taken immediately

LOG_CRIT critical conditions

LOG_ERR error conditions

LOG_WARNING
warning conditions

LOG_NOTICE normal, but significant, condition

LOG_INFO informational message

LOG_DEBUG debug-level message

The function *setlogmask*(3) can be used to restrict logging to specified levels only.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
openlog(), **closelog**()	Thread safety	MT-Safe
syslog(), **vsyslog**()	Thread safety	MT-Safe env locale

STANDARDS

syslog()
openlog()
closelog()
POSIX.1-2008.

vsyslog()
None.

HISTORY

syslog()
4.2BSD, SUSv2, POSIX.1-2001.

openlog()
closelog()
4.3BSD, SUSv2, POSIX.1-2001.

vsyslog()
4.3BSD-Reno.

POSIX.1-2001 specifies only the **LOG_USER** and **LOG_LOCAL*** values for *facility*. However, with the exception of **LOG_AUTHPRIV** and **LOG_FTP**, the other *facility* values appear on most UNIX systems.

The **LOG_PERROR** value for *option* is not specified by POSIX.1-2001 or POSIX.1-2008, but is available in most versions of UNIX.

NOTES

The argument *ident* in the call of **openlog**() is probably stored as-is. Thus, if the string it points to is changed, **syslog**() may start prepending the changed string, and if the string it points to ceases to exist, the results are undefined. Most portable is to use a string constant.

Never pass a string with user-supplied data as a format, use the following instead:

```
syslog(priority, "%s", string);
```

NAME

system − execute a shell command

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdlib.h>

int system(const char *****command***);**

DESCRIPTION

The **system**() library function behaves as if it used *fork*(2) to create a child process that executed the shell command specified in *command* using *execl*(3) as follows:

```
execl("/bin/sh", "sh", "-c", command, (char *) NULL);
```

system() returns after the command has been completed.

During execution of the command, **SIGCHLD** will be blocked, and **SIGINT** and **SIGQUIT** will be ignored, in the process that calls **system**(). (These signals will be handled according to their defaults inside the child process that executes *command*.)

If *command* is NULL, then **system**() returns a status indicating whether a shell is available on the system.

RETURN VALUE

The return value of **system**() is one of the following:

- If *command* is NULL, then a nonzero value if a shell is available, or 0 if no shell is available.
- If a child process could not be created, or its status could not be retrieved, the return value is −1 and *errno* is set to indicate the error.
- If a shell could not be executed in the child process, then the return value is as though the child shell terminated by calling *_exit*(2) with the status 127.
- If all system calls succeed, then the return value is the termination status of the child shell used to execute *command*. (The termination status of a shell is the termination status of the last command it executes.)

In the last two cases, the return value is a "wait status" that can be examined using the macros described in *waitpid*(2). (i.e., **WIFEXITED**(), **WEXITSTATUS**(), and so on).

system() does not affect the wait status of any other children.

ERRORS

system() can fail with any of the same errors as *fork*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
system()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89.

NOTES

system() provides simplicity and convenience: it handles all of the details of calling *fork*(2), *execl*(3), and *waitpid*(2), as well as the necessary manipulations of signals; in addition, the shell performs the usual substitutions and I/O redirections for *command*. The main cost of **system**() is inefficiency: additional system calls are required to create the process that runs the shell and to execute the shell.

If the **_XOPEN_SOURCE** feature test macro is defined (before including *any* header files), then the macros described in *waitpid*(2) (**WEXITSTATUS**(), etc.) are made available when including *<stdlib.h>*.

As mentioned, **system**() ignores **SIGINT** and **SIGQUIT**. This may make programs that call it from a loop uninterruptible, unless they take care themselves to check the exit status of the child. For

example:

```
while (something) {
    int ret = system("foo");

    if (WIFSIGNALED(ret) &&
        (WTERMSIG(ret) == SIGINT || WTERMSIG(ret) == SIGQUIT))
            break;
}
```

According to POSIX.1, it is unspecified whether handlers registered using *pthread_atfork*(3) are called during the execution of **system**(). In the glibc implementation, such handlers are not called.

Before glibc 2.1.3, the check for the availability of */bin/sh* was not actually performed if *command* was NULL; instead it was always assumed to be available, and **system**() always returned 1 in this case. Since glibc 2.1.3, this check is performed because, even though POSIX.1-2001 requires a conforming implementation to provide a shell, that shell may not be available or executable if the calling program has previously called *chroot*(2) (which is not specified by POSIX.1-2001).

It is possible for the shell command to terminate with a status of 127, which yields a **system**() return value that is indistinguishable from the case where a shell could not be executed in the child process.

Caveats

Do not use **system**() from a privileged program (a set-user-ID or set-group-ID program, or a program with capabilities) because strange values for some environment variables might be used to subvert system integrity. For example, **PATH** could be manipulated so that an arbitrary program is executed with privilege. Use the *exec*(3) family of functions instead, but not *execlp*(3) or *execvp*(3) (which also use the **PATH** environment variable to search for an executable).

system() will not, in fact, work properly from programs with set-user-ID or set-group-ID privileges on systems on which */bin/sh* is bash version 2: as a security measure, bash 2 drops privileges on startup. (Debian uses a different shell, *dash*(1), which does not do this when invoked as **sh**.)

Any user input that is employed as part of *command* should be *carefully* sanitized, to ensure that unexpected shell commands or command options are not executed. Such risks are especially grave when using **system**() from a privileged program.

BUGS

If the command name starts with a hyphen, *sh*(1) interprets the command name as an option, and the behavior is undefined. (See the **-c** option to *sh*(1)To work around this problem, prepend the command with a space as in the following call:

```
system(" -unfortunate-command-name");
```

sh(1), *execve*(2), *fork*(2), *sigaction*(2), *sigprocmask*(2), *wait*(2), *exec*(3), *signal*(7)

NAME

sysv_signal − signal handling with System V semantics

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <signal.h>

typedef void (*sighandler_t)(int);

sighandler_t sysv_signal(int signum, sighandler_t handler);
```

DESCRIPTION

The **sysv_signal**() function takes the same arguments, and performs the same task, as *signal*(2).

However **sysv_signal**() provides the System V unreliable signal semantics, that is: a) the disposition of the signal is reset to the default when the handler is invoked; b) delivery of further instances of the signal is not blocked while the signal handler is executing; and c) if the handler interrupts (certain) blocking system calls, then the system call is not automatically restarted.

RETURN VALUE

The **sysv_signal**() function returns the previous value of the signal handler, or **SIG_ERR** on error.

ERRORS

As for *signal*(2).

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
sysv_signal()	Thread safety	MT-Safe

VERSIONS

Use of **sysv_signal**() should be avoided; use *sigaction*(2) instead.

On older Linux systems, **sysv_signal**() and *signal*(2) were equivalent. But on newer systems, *signal*(2) provides reliable signal semantics; see *signal*(2) for details.

The use of *sighandler_t* is a GNU extension; this type is defined only if the **_GNU_SOURCE** feature test macro is defined.

STANDARDS

None.

TAILQ_ENTRY *NAME***);**

void TAILQ_CONCAT(TAILQ_HEAD ***_head1_, TAILQ_HEAD ***_head2_**,**
TAILQ_ENTRY *NAME***);**

DESCRIPTION

These macros define and operate on doubly linked tail queues.

In the macro definitions, *TYPE* is the name of a user defined structure, that must contain a field of type *TAILQ_ENTRY*, named *NAME*. The argument *HEADNAME* is the name of a user defined structure that must be declared using the macro **TAILQ_HEAD**().

Creation

A tail queue is headed by a structure defined by the **TAILQ_HEAD**() macro. This structure contains a pair of pointers, one to the first element in the queue and the other to the last element in the queue. The elements are doubly linked so that an arbitrary element can be removed without traversing the queue. New elements can be added to the queue after an existing element, before an existing element, at the head of the queue, or at the end of the queue. A *TAILQ_HEAD* structure is declared as follows:

```
TAILQ_HEAD(HEADNAME, TYPE) head;
```

where *struct HEADNAME* is the structure to be defined, and *struct TYPE* is the type of the elements to be linked into the queue. A pointer to the head of the queue can later be declared as:

```
struct HEADNAME *headp;
```

(The names *head* and *headp* are user selectable.)

TAILQ_ENTRY() declares a structure that connects the elements in the queue.

TAILQ_HEAD_INITIALIZER() evaluates to an initializer for the queue *head*.

TAILQ_INIT() initializes the queue referenced by

TAILQ_EMPTY() evaluates to true if there are no items on the queue. *head*.

Insertion

TAILQ_INSERT_HEAD() inserts the new element *elm* at the head of the queue.

TAILQ_INSERT_TAIL() inserts the new element *elm* at the end of the queue.

TAILQ_INSERT_BEFORE() inserts the new element *elm* before the element *listelm*.

TAILQ_INSERT_AFTER() inserts the new element *elm* after the element *listelm*.

Traversal

TAILQ_FIRST() returns the first item on the queue, or NULL if the queue is empty.

TAILQ_LAST() returns the last item on the queue. If the queue is empty the return value is NULL.

TAILQ_PREV() returns the previous item on the queue, or NULL if this item is the first.

TAILQ_NEXT() returns the next item on the queue, or NULL if this item is the last.

TAILQ_FOREACH() traverses the queue referenced by *head* in the forward direction, assigning each element in turn to *var*. *var* is set to NULL if the loop completes normally, or if there were no elements.

TAILQ_FOREACH_REVERSE() traverses the queue referenced by *head* in the reverse direction, assigning each element in turn to *var*.

Removal

TAILQ_REMOVE() removes the element *elm* from the queue.

Other features

TAILQ_CONCAT() concatenates the queue headed by *head2* onto the end of the one headed by *head1* removing all entries from the former.

RETURN VALUE

TAILQ_EMPTY() returns nonzero if the queue is empty, and zero if the queue contains at least one entry.

TAILQ_FIRST(), **TAILQ_LAST**(), **TAILQ_PREV**(), and **TAILQ_NEXT**() return a pointer to the first, last, previous, or next *TYPE* structure, respectively.

TAILQ_HEAD_INITIALIZER() returns an initializer that can be assigned to the queue *head*.

STANDARDS

BSD.

HISTORY

4.4BSD.

CAVEATS

TAILQ_FOREACH() and **TAILQ_FOREACH_REVERSE**() don't allow *var* to be removed or freed within the loop, as it would interfere with the traversal. **TAILQ_FOREACH_SAFE**() and **TAILQ_FOREACH_REVERSE_SAFE**(), which are present on the BSDs but are not present in glibc, fix this limitation by allowing *var* to safely be removed from the list and freed from within the loop without interfering with the traversal.

EXAMPLES

```
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <sys/queue.h>

struct entry {
    int data;
    TAILQ_ENTRY(entry) entries;             /* Tail queue */
};
```

```
TAILQ_HEAD(tailhead, entry);

int
main(void)
{
    struct entry *n1, *n2, *n3, *np;
    struct tailhead head;                   /* Tail queue head */
    int i;

    TAILQ_INIT(&head);                      /* Initialize the queue */

    n1 = malloc(sizeof(struct entry));      /* Insert at the head */
    TAILQ_INSERT_HEAD(&head, n1, entries);

    n1 = malloc(sizeof(struct entry));      /* Insert at the tail */
    TAILQ_INSERT_TAIL(&head, n1, entries);

    n2 = malloc(sizeof(struct entry));      /* Insert after */
    TAILQ_INSERT_AFTER(&head, n1, n2, entries);

    n3 = malloc(sizeof(struct entry));      /* Insert before */
    TAILQ_INSERT_BEFORE(n2, n3, entries);

    TAILQ_REMOVE(&head, n2, entries);       /* Deletion */
    free(n2);
                                            /* Forward traversal */
    i = 0;
    TAILQ_FOREACH(np, &head, entries)
        np->data = i++;
                                            /* Reverse traversal */
    TAILQ_FOREACH_REVERSE(np, &head, tailhead, entries)
        printf("%i\n", np->data);
                                            /* TailQ deletion */
    n1 = TAILQ_FIRST(&head);
    while (n1 != NULL) {
        n2 = TAILQ_NEXT(n1, entries);
        free(n1);
        n1 = n2;
    }
    TAILQ_INIT(&head);

    exit(EXIT_SUCCESS);
}
```

NAME

tan, tanf, tanl − tangent function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double tan(double x);
float tanf(float x);
long double tanl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

tanf(), **tanl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the tangent of *x*, where *x* is given in radians.

RETURN VALUE

On success, these functions return the tangent of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity or negative infinity, a domain error occurs, and a NaN is returned.

If the correct result would overflow, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the mathematically correct sign.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is an infinity
: *errno* is set to **EDOM** (but see BUGS). An invalid floating-point exception (**FE_INVALID**) is raised.

Range error: result overflow
: An overflow floating-point exception (**FE_OVERFLOW**) is raised.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tan(), **tanf**(), **tanl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

C99, POSIX.1-2001.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

BUGS

Before glibc 2.10, the glibc implementation did not set *errno* to **EDOM** when a domain error occurred.

NAME

tanh, tanhf, tanhl − hyperbolic tangent function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double tanh(double x);
float tanhf(float x);
long double tanhl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

tanhf(), **tanhl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L
|| /* Since glibc 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

These functions return the hyperbolic tangent of *x*, which is defined mathematically as:

tanh(x) = sinh(x) / cosh(x)

RETURN VALUE

On success, these functions return the hyperbolic tangent of *x*.

If *x* is a NaN, a NaN is returned.

If *x* is +0 (−0), +0 (−0) is returned.

If *x* is positive infinity (negative infinity), +1 (−1) is returned.

ERRORS

No errors occur.

ATTRIBUTES

NAME

tcgetpgrp, tcsetpgrp − get and set terminal foreground process group

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

pid_t tcgetpgrp(int fd);
int tcsetpgrp(int fd, pid_t pgrp);
```

DESCRIPTION

The function **tcgetpgrp**() returns the process group ID of the foreground process group on the terminal associated to *fd*, which must be the controlling terminal of the calling process.

The function **tcsetpgrp**() makes the process group with process group ID *pgrp* the foreground process group on the terminal associated to *fd*, which must be the controlling terminal of the calling process, and still be associated with its session. Moreover, *pgrp* must be a (nonempty) process group belonging to the same session as the calling process.

If **tcsetpgrp**() is called by a member of a background process group in its session, and the calling process is not blocking or ignoring **SIGTTOU**, a **SIGTTOU** signal is sent to all members of this background process group.

RETURN VALUE

When *fd* refers to the controlling terminal of the calling process, the function **tcgetpgrp**() will return the foreground process group ID of that terminal if there is one, and some value larger than 1 that is not presently a process group ID otherwise. When *fd* does not refer to the controlling terminal of the calling process, −1 is returned, and *errno* is set to indicate the error.

When successful, **tcsetpgrp**() returns 0. Otherwise, it returns −1, and *errno* is set to indicate the error.

ERRORS

EBADF
: *fd* is not a valid file descriptor.

EINVAL
: *pgrp* has an unsupported value.

ENOTTY
: The calling process does not have a controlling terminal, or it has one but it is not described by *fd*, or, for **tcsetpgrp**(), this controlling terminal is no longer associated with the session of the calling process.

EPERM
: *pgrp* has a supported value, but is not the process group ID of a process in the same session as the calling process.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tcgetpgrp(), **tcsetpgrp**()	Thread safety	MT-Safe

VERSIONS

These functions are implemented via the **TIOCGPGRP** and **TIOCSPGRP** ioctls.

STANDARDS

POSIX.1-2008.

HISTORY

NAME

tcgetsid − get session ID

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#define _XOPEN_SOURCE 500       /* See feature_test_macros(7) */
#include <termios.h>

pid_t tcgetsid(int fd);
```

DESCRIPTION

The function **tcgetsid**() returns the session ID of the current session that has the terminal associated to *fd* as controlling terminal. This terminal must be the controlling terminal of the calling process.

RETURN VALUE

When *fd* refers to the controlling terminal of our session, the function **tcgetsid**() will return the session ID of this session. Otherwise, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EBADF
fd is not a valid file descriptor.

ENOTTY
The calling process does not have a controlling terminal, or it has one but it is not described by *fd*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

NAME

telldir − return current location in directory stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <dirent.h>

long telldir(DIR *dirp);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

telldir():
_XOPEN_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The **telldir**() function returns the current location associated with the directory stream *dirp*.

RETURN VALUE

On success, the **telldir**() function returns the current location in the directory stream. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EBADF
Invalid directory stream descriptor *dirp*.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
telldir()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.3BSD.

Up to glibc 2.1.1, the return type of **telldir**() was *off_t*. POSIX.1-2001 specifies *long*, and this is the type used since glibc 2.1.2.

In early filesystems, the value returned by **telldir**() was a simple file offset within a directory. Modern filesystems use tree or hash structures, rather than flat tables, to represent directories. On such filesystems, the value returned by **telldir**() (and used internally by *readdir*(3)) is a "cookie" that is used by the implementation to derive a position within a directory. Application programs should treat this strictly as an opaque value, making *no* assumptions about its contents.

SEE ALSO

closedir(3), *opendir*(3), *readdir*(3), *rewinddir*(3), *scandir*(3), *seekdir*(3)

NAME

tempnam − create a name for a temporary file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

char *tempnam(const char * *dir***, const char *** *pfx***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

tempnam():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

Never use this function. Use *mkstemp*(3) or *tmpfile*(3) instead.

The **tempnam**() function returns a pointer to a string that is a valid filename, and such that a file with this name did not exist when **tempnam**() checked. The filename suffix of the pathname generated will start with *pfx* in case *pfx* is a non-NULL string of at most five bytes. The directory prefix part of the pathname generated is required to be "appropriate" (often that at least implies writable).

Attempts to find an appropriate directory go through the following steps:

a) In case the environment variable **TMPDIR** exists and contains the name of an appropriate directory, that is used.

b) Otherwise, if the *dir* argument is non-NULL and appropriate, it is used.

c) Otherwise, *P_tmpdir* (as defined in <*stdio.h*>) is used when appropriate.

d) Finally an implementation-defined directory may be used.

The string returned by **tempnam**() is allocated using *malloc*(3) and hence should be freed by *free*(3).

RETURN VALUE

On success, the **tempnam**() function returns a pointer to a unique temporary filename. It returns NULL if a unique name cannot be generated, with *errno* set to indicate the error.

ERRORS

ENOMEM
Allocation of storage failed.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tempnam()	Thread safety	MT-Safe env

STANDARDS

POSIX.1-2008.

HISTORY

SVr4, 4.3BSD, POSIX.1-2001. Obsoleted in POSIX.1-2008.

NOTES

Although **tempnam**() generates names that are difficult to guess, it is nevertheless possible that between the time that **tempnam**() returns a pathname, and the time that the program opens it, another program might create that pathname using *open*(2), or create it as a symbolic link. This can lead to security holes. To avoid such possibilities, use the *open*(2) **O_EXCL** flag to open the pathname. Or better yet, use *mkstemp*(3) or *tmpfile*(3).

SUSv2 does not mention the use of **TMPDIR**; glibc will use it only when the program is not set-user-ID. On SVr4, the directory used under **d)** is */tmp* (and this is what glibc does).

Because it dynamically allocates memory used to return the pathname, **tempnam**() is reentrant, and thus thread safe, unlike *tmpnam*(3).

The **tempnam**() function generates a different string each time it is called, up to **TMP_MAX** (defined in <*stdio.h*>) times. If it is called more than **TMP_MAX** times, the behavior is implementation defined.

tempnam() uses at most the first five bytes from *pfx*.

The glibc implementation of **tempnam**() fails with the error **EEXIST** upon failure to find a unique name.

BUGS

The precise meaning of "appropriate" is undefined; it is unspecified how accessibility of a directory is determined.

SEE ALSO

mkstemp(3), *mktemp*(3), *tmpfile*(3), *tmpnam*(3)

NAME

termios, tcgetattr, tcsetattr, tcsendbreak, tcdrain, tcflush, tcflow, cfmakeraw, cfgetospeed, cfgetispeed, cfsetispeed, cfsetospeed, cfsetspeed − get and set terminal attributes, line control, get and set baud rate

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <termios.h>
#include <unistd.h>

int tcgetattr(int fd, struct termios *termios_p);
int tcsetattr(int fd, int optional_actions,
              const struct termios *termios_p);

int tcsendbreak(int fd, int duration);
int tcdrain(int fd);

speed_t cfgetispeed(const struct termios *termios_p);
speed_t cfgetospeed(const struct termios *termios_p);

int cfsetispeed(struct termios *termios_p, speed_t speed);
int cfsetospeed(struct termios *termios_p, speed_t speed);
int cfsetspeed(struct termios *termios_p, speed_t speed);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

cfsetspeed(), **cfmakeraw**():
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The termios functions describe a general terminal interface that is provided to control asynchronous communications ports.

The termios structure

Many of the functions described here have a *termios_p* argument that is a pointer to a *termios* structure. This structure contains at least the following members:

```
tcflag_t c_iflag;      /* input modes */
tcflag_t c_oflag;      /* output modes */
tcflag_t c_cflag;      /* control modes */
tcflag_t c_lflag;      /* local modes */
cc_t     c_cc[NCCS];   /* special characters */
```

The values that may be assigned to these fields are described below. In the case of the first four bit-mask fields, the definitions of some of the associated flags that may be set are exposed only if a specific feature test macro (see *feature_test_macros*(7)) is defined, as noted in brackets ("[]").

In the descriptions below, "not in POSIX" means that the value is not specified in POSIX.1-2001, and "XSI" means that the value is specified in POSIX.1-2001 as part of the XSI extension.

c_iflag flag constants:

IGNBRK
Ignore BREAK condition on input.

BRKINT
If **IGNBRK** is set, a BREAK is ignored. If it is not set but **BRKINT** is set, then a BREAK causes the input and output queues to be flushed, and if the terminal is the controlling terminal of a foreground process group, it will cause a **SIGINT** to be sent to this foreground process group. When neither **IGNBRK** nor **BRKINT** are set, a BREAK reads as a null byte ('\0'), except when **PARMRK** is set, in which case it reads as the sequence \377 \0 \0.

IGNPAR
Ignore framing errors and parity errors.

PARMRK
If this bit is set, input bytes with parity or framing errors are marked when passed to the program. This bit is meaningful only when **INPCK** is set and **IGNPAR** is not set. The way erroneous bytes are marked is with two preceding bytes, \377 and \0. Thus, the program actually reads three bytes for one erroneous byte received from the terminal. If a valid byte has the value \377, and **ISTRIP** (see below) is not set, the program might confuse it with the prefix that marks a parity error. Therefore, a valid byte \377 is passed to the program as two bytes, \377 \377, in this case.

If neither **IGNPAR** nor **PARMRK** is set, read a character with a parity error or framing error as \0.

INPCK
Enable input parity checking.

ISTRIP
Strip off eighth bit.

INLCR
Translate NL to CR on input.

IGNCR
Ignore carriage return on input.

ICRNL
Translate carriage return to newline on input (unless **IGNCR** is set).

IUCLC
(not in POSIX) Map uppercase characters to lowercase on input.

IXON Enable XON/XOFF flow control on output.

IXANY
(XSI) Typing any character will restart stopped output. (The default is to allow just the START character to restart output.)

IXOFF
Enable XON/XOFF flow control on input.

IMAXBEL
(not in POSIX) Ring bell when input queue is full. Linux does not implement this bit, and acts as if it is always set.

IUTF8 (since Linux 2.6.4)
(not in POSIX) Input is UTF8; this allows character-erase to be correctly performed in cooked mode.

c_oflag flag constants:

OPOST
Enable implementation-defined output processing.

OLCUC
(not in POSIX) Map lowercase characters to uppercase on output.

ONLCR
(XSI) Map NL to CR-NL on output.

OCRNL
Map CR to NL on output.

ONOCR
Don’t output CR at column 0.

ONLRET
The NL character is assumed to do the carriage-return function; the kernel’s idea of the current column is set to 0 after both NL and CR.

OFILL
Send fill characters for a delay, rather than using a timed delay.

OFDEL
Fill character is ASCII DEL (0177). If unset, fill character is ASCII NUL ('\0'). (Not implemented on Linux.)

NLDLY
Newline delay mask. Values are **NL0** and **NL1**. [requires **_BSD_SOURCE** or **_SVID_SOURCE** or **_XOPEN_SOURCE**]

CRDLY
Carriage return delay mask. Values are **CR0**, **CR1**, **CR2**, or **CR3**. [requires **_BSD_SOURCE** or **_SVID_SOURCE** or **_XOPEN_SOURCE**]

TABDLY
Horizontal tab delay mask. Values are **TAB0**, **TAB1**, **TAB2**, **TAB3** (or **XTABS**, but see the **BUGS** section). A value of TAB3, that is, XTABS, expands tabs to spaces (with tab stops every eight columns). [requires **_BSD_SOURCE** or **_SVID_SOURCE** or **_XOPEN_SOURCE**]

BSDLY
Backspace delay mask. Values are **BS0** or **BS1**. (Has never been implemented.) [requires **_BSD_SOURCE** or **_SVID_SOURCE** or **_XOPEN_SOURCE**]

VTDLY
Vertical tab delay mask. Values are **VT0** or **VT1**.

FFDLY
Form feed delay mask. Values are **FF0** or **FF1**. [requires **_BSD_SOURCE** or **_SVID_SOURCE** or **_XOPEN_SOURCE**]

c_cflag flag constants:

CBAUD
(not in POSIX) Baud speed mask (4+1 bits). [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

CBAUDEX
(not in POSIX) Extra baud speed mask (1 bit), included in **CBAUD**. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

(POSIX says that the baud speed is stored in the *termios* structure without specifying where precisely, and provides **cfgetispeed**() and **cfsetispeed**() for getting at it. Some systems use bits selected by **CBAUD** in *c_cflag*, other systems use separate fields, for example, *sg_ispeed* and *sg_ospeed*.)

CSIZE Character size mask. Values are **CS5**, **CS6**, **CS7**, or **CS8**.

CSTOPB
Set two stop bits, rather than one.

CREAD
Enable receiver.

PARENB
Enable parity generation on output and parity checking for input.

PARODD
If set, then parity for input and output is odd; otherwise even parity is used.

HUPCL
Lower modem control lines after last process closes the device (hang up).

CLOCAL
Ignore modem control lines.

LOBLK
(not in POSIX) Block output from a noncurrent shell layer. For use by **shl** (shell layers). (Not implemented on Linux.)

CIBAUD
(not in POSIX) Mask for input speeds. The values for the **CIBAUD** bits are the same as the values for the **CBAUD** bits, shifted left **IBSHIFT** bits. [requires **_BSD_SOURCE** or **_SVID_SOURCE**] (Not implemented in glibc, supported on Linux via **TCGET*** and **TCSET*** ioctls; see *ioctl_tty*(2))

CMSPAR
(not in POSIX) Use "stick" (mark/space) parity (supported on certain serial devices): if **PARODD** is set, the parity bit is always 1; if **PARODD** is not set, then the parity bit is always 0. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

CRTSCTS
(not in POSIX) Enable RTS/CTS (hardware) flow control. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

c_lflag flag constants:

ISIG When any of the characters INTR, QUIT, SUSP, or DSUSP are received, generate the corresponding signal.

ICANON
Enable canonical mode (described below).

XCASE
(not in POSIX; not supported under Linux) If **ICANON** is also set, terminal is uppercase only. Input is converted to lowercase, except for characters preceded by \. On output, uppercase characters are preceded by \ and lowercase characters are converted to uppercase. [requires **_BSD_SOURCE** or **_SVID_SOURCE** or **_XOPEN_SOURCE**]

ECHO Echo input characters.

ECHOE
If **ICANON** is also set, the ERASE character erases the preceding input character, and WERASE erases the preceding word.

ECHOK
If **ICANON** is also set, the KILL character erases the current line.

ECHONL
If **ICANON** is also set, echo the NL character even if ECHO is not set.

ECHOCTL
(not in POSIX) If **ECHO** is also set, terminal special characters other than TAB, NL, START, and STOP are echoed as **^X**, where X is the character with ASCII code 0x40 greater than the special character. For example, character 0x08 (BS) is echoed as **^H**. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

ECHOPRT
(not in POSIX) If **ICANON** and **ECHO** are also set, characters are printed as they are being erased. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

ECHOKE
(not in POSIX) If **ICANON** is also set, KILL is echoed by erasing each character on the line, as specified by **ECHOE** and **ECHOPRT**. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

DEFECHO
(not in POSIX) Echo only when a process is reading. (Not implemented on Linux.)

FLUSHO
(not in POSIX; not supported under Linux) Output is being flushed. This flag is toggled by typing the DISCARD character. [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

NOFLSH
Disable flushing the input and output queues when generating signals for the INT, QUIT, and SUSP characters.

TOSTOP
Send the **SIGTTOU** signal to the process group of a background process which tries to write to its controlling terminal.

PENDIN
(not in POSIX; not supported under Linux) All characters in the input queue are reprinted when the next character is read. (**bash**(1) handles typeahead this way.) [requires **_BSD_SOURCE** or **_SVID_SOURCE**]

IEXTEN
Enable implementation-defined input processing. This flag, as well as **ICANON** must be enabled for the special characters EOL2, LNEXT, REPRINT, WERASE to be interpreted, and for the **IUCLC** flag to be effective.

The *c_cc* array defines the terminal special characters. The symbolic indices (initial values) and meaning are:

VDISCARD
(not in POSIX; not supported under Linux; 017, SI, Ctrl-O) Toggle: start/stop discarding pending output. Recognized when **IEXTEN** is set, and then not passed as input.

VDSUSP
(not in POSIX; not supported under Linux; 031, EM, Ctrl-Y) Delayed suspend character (DSUSP): send **SIGTSTP** signal when the character is read by the user program. Recognized when **IEXTEN** and **ISIG** are set, and the system supports job control, and then not passed as input.

VEOF (004, EOT, Ctrl-D) End-of-file character (EOF). More precisely: this character causes the pending tty buffer to be sent to the waiting user program without waiting for end-of-line. If it is the first character of the line, the *read*(2) in the user program returns 0, which signifies end-of-file. Recognized when **ICANON** is set, and then not passed as input.

VEOL (0, NUL) Additional end-of-line character (EOL). Recognized when **ICANON** is set.

VEOL2
(not in POSIX; 0, NUL) Yet another end-of-line character (EOL2). Recognized when **ICANON** is set.

VERASE
(0177, DEL, rubout, or 010, BS, Ctrl-H, or also #) Erase character (ERASE). This erases the previous not-yet-erased character, but does not erase past EOF or beginning-of-line. Recognized when **ICANON** is set, and then not passed as input.

VINTR
(003, ETX, Ctrl-C, or also 0177, DEL, rubout) Interrupt character (INTR). Send a **SIGINT** signal. Recognized when **ISIG** is set, and then not passed as input.

VKILL
(025, NAK, Ctrl-U, or Ctrl-X, or also @) Kill character (KILL). This erases the input since the last EOF or beginning-of-line. Recognized when **ICANON** is set, and then not passed as input.

VLNEXT
(not in POSIX; 026, SYN, Ctrl-V) Literal next (LNEXT). Quotes the next input character, depriving it of a possible special meaning. Recognized when **IEXTEN** is set, and then not passed as input.

VMIN Minimum number of characters for noncanonical read (MIN).

VQUIT
(034, FS, Ctrl-\) Quit character (QUIT). Send **SIGQUIT** signal. Recognized when **ISIG** is set, and then not passed as input.

VREPRINT
(not in POSIX; 022, DC2, Ctrl-R) Reprint unread characters (REPRINT). Recognized when **ICANON** and **IEXTEN** are set, and then not passed as input.

VSTART
(021, DC1, Ctrl-Q) Start character (START). Restarts output stopped by the Stop character. Recognized when **IXON** is set, and then not passed as input.

VSTATUS
(not in POSIX; not supported under Linux; status request: 024, DC4, Ctrl-T). Status character (STATUS). Display status information at terminal, including state of foreground process and amount of CPU time it has consumed. Also sends a **SIGINFO** signal (not supported on Linux) to the foreground process group.

VSTOP
(023, DC3, Ctrl-S) Stop character (STOP). Stop output until Start character typed. Recognized when **IXON** is set, and then not passed as input.

VSUSP
(032, SUB, Ctrl-Z) Suspend character (SUSP). Send **SIGTSTP** signal. Recognized when **ISIG** is set, and then not passed as input.

VSWTCH
(not in POSIX; not supported under Linux; 0, NUL) Switch character (SWTCH). Used in System V to switch shells in *shell layers*, a predecessor to shell job control.

VTIME
Timeout in deciseconds for noncanonical read (TIME).

VWERASE
(not in POSIX; 027, ETB, Ctrl-W) Word erase (WERASE). Recognized when **ICANON** and **IEXTEN** are set, and then not passed as input.

An individual terminal special character can be disabled by setting the value of the corresponding *c_cc* element to **_POSIX_VDISABLE**.

The above symbolic subscript values are all different, except that **VTIME**, **VMIN** may have the same value as **VEOL**, **VEOF**, respectively. In noncanonical mode the special character meaning is replaced by the timeout meaning. For an explanation of **VMIN** and **VTIME**, see the description of noncanonical mode below.

Retrieving and changing terminal settings

tcgetattr() gets the parameters associated with the object referred by *fd* and stores them in the *termios* structure referenced by *termios_p*. This function may be invoked from a background process; however, the terminal attributes may be subsequently changed by a foreground process.

tcsetattr() sets the parameters associated with the terminal (unless support is required from the underlying hardware that is not available) from the *termios* structure referred to by *termios_p*. *optional_actions* specifies when the changes take effect:

TCSANOW
the change occurs immediately.

TCSADRAIN
the change occurs after all output written to *fd* has been transmitted. This option should be used when changing parameters that affect output.

TCSAFLUSH
the change occurs after all output written to the object referred by *fd* has been transmitted, and all input that has been received but not read will be discarded before the change is made.

Canonical and noncanonical mode

The setting of the **ICANON** canon flag in *c_lflag* determines whether the terminal is operating in canonical mode (**ICANON** set) or noncanonical mode (**ICANON** unset). By default, **ICANON** is set.

In canonical mode:

- Input is made available line by line. An input line is available when one of the line delimiters is typed (NL, EOL, EOL2; or EOF at the start of line). Except in the case of EOF, the line delimiter is included in the buffer returned by *read*(2).
- Line editing is enabled (ERASE, KILL; and if the **IEXTEN** flag is set: WERASE, REPRINT, LNEXT). A *read*(2) returns at most one line of input; if the *read*(2) requested fewer bytes than are available in the current line of input, then only as many bytes as requested are read, and the remaining characters will be available for a future *read*(2).

- The maximum line length is 4096 chars (including the terminating newline character); lines longer than 4096 chars are truncated. After 4095 characters, input processing (e.g., **ISIG** and **ECHO*** processing) continues, but any input data after 4095 characters up to (but not including) any terminating newline is discarded. This ensures that the terminal can always receive more input until at least one line can be read.

In noncanonical mode input is available immediately (without the user having to type a line-delimiter character), no input processing is performed, and line editing is disabled. The read buffer will only accept 4095 chars; this provides the necessary space for a newline char if the input mode is switched to canonical. The settings of MIN (*c_cc[VMIN]*) and TIME (*c_cc[VTIME]*) determine the circumstances in which a *read*(2) completes; there are four distinct cases:

MIN == 0, TIME == 0 (polling read)
: If data is available, *read*(2) returns immediately, with the lesser of the number of bytes available, or the number of bytes requested. If no data is available, *read*(2) returns 0.

MIN > 0, TIME == 0 (blocking read)
: *read*(2) blocks until MIN bytes are available, and returns up to the number of bytes requested.

MIN == 0, TIME > 0 (read with timeout)
: TIME specifies the limit for a timer in tenths of a second. The timer is started when *read*(2) is called. *read*(2) returns either when at least one byte of data is available, or when the timer expires. If the timer expires without any input becoming available, *read*(2) returns 0. If data is already available at the time of the call to *read*(2), the call behaves as though the data was received immediately after the call.

MIN > 0, TIME > 0 (read with interbyte timeout)
: TIME specifies the limit for a timer in tenths of a second. Once an initial byte of input becomes available, the timer is restarted after each further byte is received. *read*(2) returns when any of the following conditions is met:

  - MIN bytes have been received.
  - The interbyte timer expires.
  - The number of bytes requested by *read*(2) has been received. (POSIX does not specify this termination condition, and on some other implementations *read*(2) does not return in this case.)

  Because the timer is started only after the initial byte becomes available, at least one byte will be read. If data is already available at the time of the call to *read*(2), the call behaves as though the data was received immediately after the call.

POSIX does not specify whether the setting of the **O_NONBLOCK** file status flag takes precedence over the MIN and TIME settings. If **O_NONBLOCK** is set, a *read*(2) in noncanonical mode may return immediately, regardless of the setting of MIN or TIME. Furthermore, if no data is available, POSIX permits a *read*(2) in noncanonical mode to return either 0, or −1 with *errno* set to **EAGAIN**.

Raw mode

cfmakeraw() sets the terminal to something like the "raw" mode of the old Version 7 terminal driver: input is available character by character, echoing is disabled, and all special processing of terminal input and output characters is disabled. The terminal attributes are set as follows:

```
termios_p->c_iflag &= ~(IGNBRK | BRKINT | PARMRK | ISTRIP
                 | INLCR | IGNCR | ICRNL | IXON);
termios_p->c_oflag &= ~OPOST;
termios_p->c_lflag &= ~(ECHO | ECHONL | ICANON | ISIG | IEXTEN);
termios_p->c_cflag &= ~(CSIZE | PARENB);
termios_p->c_cflag |= CS8;
```

Line control

tcsendbreak() transmits a continuous stream of zero-valued bits for a specific duration, if the terminal is using asynchronous serial data transmission. If *duration* is zero, it transmits zero-valued bits for at least 0.25 seconds, and not more than 0.5 seconds. If *duration* is not zero, it sends zero-valued bits for some implementation-defined length of time.

If the terminal is not using asynchronous serial data transmission, **tcsendbreak**() returns without taking

any action.

tcdrain() waits until all output written to the object referred to by *fd* has been transmitted.

tcflush() discards data written to the object referred to by *fd* but not transmitted, or data received but not read, depending on the value of *queue_selector*:

TCIFLUSH
flushes data received but not read.

TCOFLUSH
flushes data written but not transmitted.

TCIOFLUSH
flushes both data received but not read, and data written but not transmitted.

tcflow() suspends transmission or reception of data on the object referred to by *fd*, depending on the value of *action*:

TCOOFF
suspends output.

TCOON
restarts suspended output.

TCIOFF
transmits a STOP character, which stops the terminal device from transmitting data to the system.

TCION
transmits a START character, which starts the terminal device transmitting data to the system.

The default on open of a terminal file is that neither its input nor its output is suspended.

Line speed

The baud rate functions are provided for getting and setting the values of the input and output baud rates in the *termios* structure. The new values do not take effect until **tcsetattr**() is successfully called.

Setting the speed to **B0** instructs the modem to "hang up". The actual bit rate corresponding to **B38400** may be altered with *setserial*(8)

The input and output baud rates are stored in the *termios* structure.

cfgetospeed() returns the output baud rate stored in the *termios* structure pointed to by *termios_p*.

cfsetospeed() sets the output baud rate stored in the *termios* structure pointed to by *termios_p* to *speed*, which must be one of these constants:

B0
B50
B75
B110
B134
B150
B200
B300
B600
B1200
B1800
B2400
B4800
B9600
B19200
B38400
B57600
B115200
B230400

B460800
B500000
B576000
B921600
B1000000
B1152000
B1500000
B2000000

These constants are additionally supported on the SPARC architecture:

B76800
B153600
B307200
B614400

These constants are additionally supported on non-SPARC architectures:

B2500000
B3000000
B3500000
B4000000

Due to differences between architectures, portable applications should check if a particular **B***nnn* constant is defined prior to using it.

The zero baud rate, **B0**, is used to terminate the connection. If **B0** is specified, the modem control lines shall no longer be asserted. Normally, this will disconnect the line. **CBAUDEX** is a mask for the speeds beyond those defined in POSIX.1 (57600 and above). Thus, **B57600** & **CBAUDEX** is nonzero.

Setting the baud rate to a value other than those defined by **B***nnn* constants is possible via the **TCSETS2** ioctl; see *ioctl_tty*(2).

cfgetispeed() returns the input baud rate stored in the *termios* structure.

cfsetispeed() sets the input baud rate stored in the *termios* structure to *speed*, which must be specified as one of the **B***nnn* constants listed above for **cfsetospeed**(). If the input baud rate is set to the literal constant **0** (not the symbolic constant **B0**), the input baud rate will be equal to the output baud rate.

cfsetspeed() is a 4.4BSD extension. It takes the same arguments as **cfsetispeed**(), and sets both input and output speed.

RETURN VALUE

cfgetispeed() returns the input baud rate stored in the *termios* structure.

cfgetospeed() returns the output baud rate stored in the *termios* structure.

All other functions return:

0 on success.

−1 on failure and set *errno* to indicate the error.

Note that **tcsetattr**() returns success if *any* of the requested changes could be successfully carried out. Therefore, when making multiple changes it may be necessary to follow this call with a further call to **tcgetattr**() to check that all changes have been performed successfully.

NOTES

UNIX V7 and several later systems have a list of baud rates where after the values **B0** through **B9600** one finds the two constants **EXTA**, **EXTB** ("External A" and "External B"). Many systems extend the list with much higher baud rates.

The effect of a nonzero *duration* with **tcsendbreak**() varies. SunOS specifies a break of *duration* * *N* seconds, where *N* is at least 0.25, and not more than 0.5. Linux, AIX, DU, Tru64 send a break of *duration* milliseconds. FreeBSD and NetBSD and HP-UX and MacOS ignore the value of *duration*. Under Solaris and UnixWare, **tcsendbreak**() with nonzero *duration* behaves like **tcdrain**().

BUGS

On the Alpha architecture before Linux 4.16 (and glibc before glibc 2.28), the **XTABS** value was different from **TAB3** and it was ignored by the **N_TTY** line discipline code of the terminal driver as a result (because as it wasn't part of the **TABDLY** mask).

NAME

tgamma, tgammaf, tgammal − true gamma function

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

#include <math.h>

double tgamma(double *x***);**
float tgammaf(float *x***);**
long double tgammal(long double *x***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

tgamma(), **tgammaf**(), **tgammal**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions calculate the Gamma function of *x*.

The Gamma function is defined by

Gamma(x) = integral from 0 to infinity of t^(x−1) e^−t dt

It is defined for every real number except for nonpositive integers. For nonnegative integral *m* one has

Gamma(m+1) = m!

and, more generally, for all *x*:

Gamma(x+1) = x * Gamma(x)

Furthermore, the following is valid for all values of *x* outside the poles:

Gamma(x) * Gamma(1 − x) = PI / sin(PI * x)

RETURN VALUE

On success, these functions return Gamma(x).

If *x* is a NaN, a NaN is returned.

If *x* is positive infinity, positive infinity is returned.

If *x* is a negative integer, or is negative infinity, a domain error occurs, and a NaN is returned.

If the result overflows, a range error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the correct mathematical sign.

If the result underflows, a range error occurs, and the functions return 0, with the correct mathematical sign.

If *x* is −0 or +0, a pole error occurs, and the functions return **HUGE_VAL**, **HUGE_VALF**, or **HUGE_VALL**, respectively, with the same sign as the 0.

ERRORS

See *math_error*(7) for information on how to determine whether an error has occurred when calling these functions.

The following errors can occur:

Domain error: *x* is a negative integer, or negative infinity
: *errno* is set to **EDOM**. An invalid floating-point exception (**FE_INVALID**) is raised (but see BUGS).

Pole error: *x* is +0 or −0
: *errno* is set to **ERANGE**. A divide-by-zero floating-point exception (**FE_DIVBYZERO**) is raised.

Range error: result overflow
: *errno* is set to **ERANGE**. An overflow floating-point exception (**FE_OVERFLOW**) is raised.

glibc also gives the following error which is not specified in C99 or POSIX.1-2001.

Range error: result underflow
: An underflow floating-point exception (**FE_UNDERFLOW**) is raised, and *errno* is set to **ERANGE**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tgamma(), **tgammaf**(), **tgammal**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

NOTES

This function had to be called "true gamma function" since there is already a function *gamma*(3) that returns something else (see *gamma*(3) for details).

BUGS

Before glibc 2.18, the glibc implementation of these functions did not set *errno* to **EDOM** when *x* is negative infinity.

Before glibc 2.19, the glibc implementation of these functions did not set *errno* to **ERANGE** on an underflow range error.

In glibc versions 2.3.3 and earlier, an argument of +0 or −0 incorrectly produced a domain error (*errno* set to **EDOM** and an **FE_INVALID** exception raised), rather than a pole error.

_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

The functions **timelocal**() and **timegm**() are the inverses of *localtime*(3) and *gmtime*(3). Both functions take a broken-down time and convert it to calendar time (seconds since the Epoch, 1970-01-01 00:00:00 +0000, UTC). The difference between the two functions is that **timelocal**() takes the local timezone into account when doing the conversion, while **timegm**() takes the input value to be Coordinated Universal Time (UTC).

RETURN VALUE

On success, these functions return the calendar time (seconds since the Epoch), expressed as a value of type *time_t*. On error, they return the value *(time_t) −1* and set *errno* to indicate the error.

ERRORS

EOVERFLOW
The result cannot be represented.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
timelocal(), **timegm**()	Thread safety	MT-Safe env locale

STANDARDS

BSD.

HISTORY

GNU, BSD.

The **timelocal**() function is equivalent to the POSIX standard function *mktime*(3). There is no reason to ever use it.

SEE ALSO

gmtime(3), *localtime*(3), *mktime*(3), *tzset*(3)

NAME

timeradd, timersub, timercmp, timerclear, timerisset − timeval operations

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <sys/time.h>

void timeradd(struct timeval *a, struct timeval *b,
        struct timeval *res);
void timersub(struct timeval *a, struct timeval *b,
        struct timeval *res);

void timerclear(struct timeval *tvp);
int timerisset(struct timeval *tvp);

int timercmp(struct timeval *a, struct timeval *b, CMP);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

All functions shown above:
Since glibc 2.19:
_DEFAULT_SOURCE
glibc 2.19 and earlier:
_BSD_SOURCE

DESCRIPTION

The macros are provided to operate on *timeval* structures, defined in <*sys/time.h*> as:

```
struct timeval {
    time_t      tv_sec;     /* seconds */
    suseconds_t tv_usec;    /* microseconds */
};
```

timeradd() adds the time values in *a* and *b*, and places the sum in the *timeval* pointed to by *res*. The result is normalized such that *res−>tv_usec* has a value in the range 0 to 999,999.

timersub() subtracts the time value in *b* from the time value in *a*, and places the result in the *timeval* pointed to by *res*. The result is normalized such that *res−>tv_usec* has a value in the range 0 to 999,999.

timerclear() zeros out the *timeval* structure pointed to by *tvp*, so that it represents the Epoch: 1970-01-01 00:00:00 +0000 (UTC).

timerisset() returns true (nonzero) if either field of the *timeval* structure pointed to by *tvp* contains a nonzero value.

timercmp() compares the timer values in *a* and *b* using the comparison operator *CMP*, and returns true (nonzero) or false (0) depending on the result of the comparison. Some systems (but not Linux/glibc), have a broken **timercmp**() implementation, in which *CMP* of >=, <=, and == do not work; portable applications can instead use

```
!timercmp(..., <)
!timercmp(..., >)
!timercmp(..., !=)
```

RETURN VALUE

timerisset() and **timercmp**() return true (nonzero) or false (0).

ERRORS

No errors are defined.

STANDARDS

None.

HISTORY

BSD.

SEE ALSO

gettimeofday(2), *time*(7)

NAME

TIMEVAL_TO_TIMESPEC, TIMESPEC_TO_TIMEVAL − convert between time structures

SYNOPSIS

```
#define _GNU_SOURCE
#include <sys/time.h>

void TIMEVAL_TO_TIMESPEC(const struct timeval *tv, struct timespec *ts);
void TIMESPEC_TO_TIMEVAL(struct timeval *tv, const struct timespec *ts);
```

DESCRIPTION

These macros convert from a *timeval*(3type) to a *timespec*(3type) structure, and vice versa, respectively.

This is especially useful for writing interfaces that receive a type, but are implemented with calls to functions that receive the other one.

STANDARDS

GNU, BSD.

NAME

tmpfile − create a temporary file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <stdio.h>

FILE *tmpfile(void);

DESCRIPTION

The **tmpfile**() function opens a unique temporary file in binary read/write (w+b) mode. The file will be automatically deleted when it is closed or the program terminates.

RETURN VALUE

The **tmpfile**() function returns a stream descriptor, or NULL if a unique filename cannot be generated or the unique file cannot be opened. In the latter case, *errno* is set to indicate the error.

ERRORS

EACCES
Search permission denied for directory in file's path prefix.

EEXIST
Unable to generate a unique filename.

EINTR
The call was interrupted by a signal; see *signal*(7).

EMFILE
The per-process limit on the number of open file descriptors has been reached.

ENFILE
The system-wide limit on the total number of open files has been reached.

ENOSPC
There was no room in the directory to add the new filename.

EROFS
Read-only filesystem.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tmpfile()	Thread safety	MT-Safe

VERSIONS

The standard does not specify the directory that **tmpfile**() will use. glibc will try the path prefix *P_tmpdir* defined in <*stdio.h*>, and if that fails, then the directory */tmp*.

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C89, SVr4, 4.3BSD, SUSv2.

NOTES

POSIX.1-2001 specifies: an error message may be written to *stdout* if the stream cannot be opened.

SEE ALSO

exit(3), *mkstemp*(3), *mktemp*(3), *tempnam*(3), *tmpnam*(3)

NAME

tmpnam, tmpnam_r − create a name for a temporary file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <stdio.h>

[[deprecated]] char *tmpnam(char *s);
[[deprecated]] char *tmpnam_r(char *s);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

tmpnam_r()
Since glibc 2.19:
_DEFAULT_SOURCE
Up to and including glibc 2.19:
_BSD_SOURCE || _SVID_SOURCE

DESCRIPTION

Note: avoid using these functions; use *mkstemp*(3) or *tmpfile*(3) instead.

The **tmpnam**() function returns a pointer to a string that is a valid filename, and such that a file with this name did not exist at some point in time, so that naive programmers may think it a suitable name for a temporary file. If the argument *s* is NULL, this name is generated in an internal static buffer and may be overwritten by the next call to **tmpnam**(). If *s* is not NULL, the name is copied to the character array (of length at least *L_tmpnam*) pointed to by *s* and the value *s* is returned in case of success.

The created pathname has a directory prefix *P_tmpdir*. (Both *L_tmpnam* and *P_tmpdir* are defined in *<stdio.h>*, just like the **TMP_MAX** mentioned below.)

The **tmpnam_r**() function performs the same task as **tmpnam**(), but returns NULL (to indicate an error) if *s* is NULL.

RETURN VALUE

These functions return a pointer to a unique temporary filename, or NULL if a unique name cannot be generated.

ERRORS

No errors are defined.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tmpnam()	Thread safety	MT-Unsafe race:tmpnam/!s
tmpnam_r()	Thread safety	MT-Safe

STANDARDS

tmpnam()
C11, POSIX.1-2008.

tmpnam_r()
None.

HISTORY

tmpnam()
SVr4, 4.3BSD, C89, POSIX.1-2001. Obsolete in POSIX.1-2008.

tmpnam_r()
Solaris.

NOTES

The **tmpnam**() function generates a different string each time it is called, up to **TMP_MAX** times. If it is called more than **TMP_MAX** times, the behavior is implementation defined.

Although these functions generate names that are difficult to guess, it is nevertheless possible that between the time that the pathname is returned and the time that the program opens it, another program might create that pathname using *open*(2), or create it as a symbolic link. This can lead to security

holes. To avoid such possibilities, use the *open*(2) **O_EXCL** flag to open the pathname. Or better yet, use *mkstemp*(3) or *tmpfile*(3).

Portable applications that use threads cannot call **tmpnam**() with a NULL argument if either **_POSIX_THREADS** or **_POSIX_THREAD_SAFE_FUNCTIONS** is defined.

BUGS

Never use these functions. Use *mkstemp*(3) or *tmpfile*(3) instead.

SEE ALSO

mkstemp(3), *mktemp*(3), *tempnam*(3), *tmpfile*(3)

NAME

toascii − convert character to ASCII

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <ctype.h>

[[deprecated]] int toascii(int c);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

toascii():
_XOPEN_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE || _BSD_SOURCE

DESCRIPTION

toascii() converts *c* to a 7-bit *unsigned char* value that fits into the ASCII character set, by clearing the high-order bits.

RETURN VALUE

The value returned is that of the converted character.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
toascii()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

SVr4, BSD, POSIX.1-2001. Obsolete in POSIX.1-2008, noting that it cannot be used portably in a localized application.

BUGS

Many people will be unhappy if you use this function. This function will convert accented letters into random characters.

SEE ALSO

isascii(3), *tolower*(3), *toupper*(3)

NAME

toupper, tolower, toupper_l, tolower_l − convert uppercase or lowercase

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <ctype.h>

int toupper(int c);
int tolower(int c);

int toupper_l(int c, locale_t locale);
int tolower_l(int c, locale_t locale);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

toupper_l(), **tolower_l**():
Since glibc 2.10:
_XOPEN_SOURCE >= 700
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

These functions convert lowercase letters to uppercase, and vice versa.

If *c* is a lowercase letter, **toupper**() returns its uppercase equivalent, if an uppercase representation exists in the current locale. Otherwise, it returns *c*. The **toupper_l**() function performs the same task, but uses the locale referred to by the locale handle *locale*.

If *c* is an uppercase letter, **tolower**() returns its lowercase equivalent, if a lowercase representation exists in the current locale. Otherwise, it returns *c*. The **tolower_l**() function performs the same task, but uses the locale referred to by the locale handle *locale*.

If *c* is neither an *unsigned char* value nor **EOF**, the behavior of these functions is undefined.

The behavior of **toupper_l**() and **tolower_l**() is undefined if *locale* is the special locale object **LC_GLOBAL_LOCALE** (see *duplocale*(3)) or is not a valid locale object handle.

RETURN VALUE

The value returned is that of the converted letter, or *c* if the conversion was not possible.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
toupper(), **tolower**(), **toupper_l**(), **tolower_l**()	Thread safety	MT-Safe

STANDARDS

toupper()
tolower()
C11, POSIX.1-2008.

toupper_l()
tolower_l()
POSIX.1-2008.

HISTORY

toupper()
tolower()
C89, 4.3BSD, POSIX.1-2001.

toupper_l()
tolower_l()
POSIX.1-2008.

NOTES

The standards require that the argument *c* for these functions is either **EOF** or a value that is representable in the type *unsigned char*. If the argument *c* is of type *char*, it must be cast to *unsigned char*, as in the following example:

```
char c;
...
res = toupper((unsigned char) c);
```

This is necessary because *char* may be the equivalent *signed char*, in which case a byte where the top bit is set would be sign extended when converting to *int*, yielding a value that is outside the range of *unsigned char*.

The details of what constitutes an uppercase or lowercase letter depend on the locale. For example, the default "**C**" locale does not know about umlauts, so no conversion is done for them.

In some non-English locales, there are lowercase letters with no corresponding uppercase equivalent; the German sharp s is one example.

NAME

towctrans − wide-character transliteration

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wctype.h>

wint_t towctrans(wint_t *wc***, wctrans_t** *desc***);**

DESCRIPTION

If *wc* is a wide character, then the **towctrans**() function translates it according to the transliteration descriptor *desc*. If *wc* is **WEOF**, **WEOF** is returned.

desc must be a transliteration descriptor returned by the *wctrans*(3) function.

RETURN VALUE

The **towctrans**() function returns the translated wide character, or **WEOF** if *wc* is **WEOF**.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
towctrans()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **towctrans**() depends on the **LC_CTYPE** category of the current locale.

NAME

towlower, towlower_l − convert a wide character to lowercase

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <wctype.h>

wint_t towlower(wint_t wc);
wint_t towlower_l(wint_t wc, locale_t locale);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

towlower_l():
Since glibc 2.10:
_XOPEN_SOURCE >= 700
Before glibc 2.10:
_GNU_SOURCE

DESCRIPTION

The **towlower**() function is the wide-character equivalent of the *tolower*(3) function. If *wc* is an uppercase wide character, and there exists a lowercase equivalent in the current locale, it returns the lowercase equivalent of *wc*. In all other cases, *wc* is returned unchanged.

The **towlower_l**() function performs the same task, but performs the conversion based on the character type information in the locale specified by *locale*. The behavior of **towlower_l**() is undefined if *locale* is the special locale object **LC_GLOBAL_LOCALE** (see *duplocale*(3)) or is not a valid locale object handle.

The argument *wc* must be representable as a *wchar_t* and be a valid character in the locale or be the value **WEOF**.

RETURN VALUE

If *wc* was convertible to lowercase, **towlower**() returns its lowercase equivalent; otherwise it returns *wc*.

NAME

trunc, truncf, truncl − round to integer, toward zero

LIBRARY

Math library (*libm*, *−lm*)

SYNOPSIS

```
#include <math.h>

double trunc(double x);
float truncf(float x);
long double truncl(long double x);
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

trunc(), **truncf**(), **truncl**():
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L

DESCRIPTION

These functions round *x* to the nearest integer value that is not larger in magnitude than *x*.

RETURN VALUE

These functions return the rounded integer value, in floating format.

If *x* is integral, infinite, or NaN, *x* itself is returned.

ERRORS

No errors occur.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
trunc(), **truncf**(), **truncl**()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

glibc 2.1. C99, POSIX.1-2001.

NOTES

The integral value returned by these functions may be too large to store in an integer type (*int*, *long*, etc.). To avoid an overflow, which will produce undefined results, an application should perform a range check on the returned value before assigning it to an integer type.

NAME

tsearch, tfind, tdelete, twalk, twalk_r, tdestroy − manage a binary search tree

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <search.h>

typedef enum { preorder, postorder, endorder, leaf } VISIT;

void *tsearch(const void *key, void **rootp,
        int (*compar)(const void *, const void *));
void *tfind(const void *key, void *const *rootp,
        int (*compar)(const void *, const void *));
void *tdelete(const void *restrict key, void **restrict rootp,
        int (*compar)(const void *, const void *));
void twalk(const void *root,
        void (*action)(const void *nodep, VISIT which,
                int depth));

#define _GNU_SOURCE         /* See feature_test_macros(7) */
#include <search.h>

void twalk_r(const void *root,
        void (*action)(const void *nodep, VISIT which,
                void *closure),
        void *closure);
void tdestroy(void *root, void (*free_node)(void *nodep));
```

DESCRIPTION

tsearch(), **tfind**(), **twalk**(), and **tdelete**() manage a binary search tree. They are generalized from Knuth (6.2.2) Algorithm T. The first field in each node of the tree is a pointer to the corresponding data item. (The calling program must store the actual data.) *compar* points to a comparison routine, which takes pointers to two items. It should return an integer which is negative, zero, or positive, depending on whether the first item is less than, equal to, or greater than the second.

tsearch() searches the tree for an item. *key* points to the item to be searched for. *rootp* points to a variable which points to the root of the tree. If the tree is empty, then the variable that *rootp* points to should be set to NULL. If the item is found in the tree, then **tsearch**() returns a pointer to the corresponding tree node. (In other words, **tsearch**() returns a pointer to a pointer to the data item.) If the item is not found, then **tsearch**() adds it, and returns a pointer to the corresponding tree node.

tfind() is like **tsearch**(), except that if the item is not found, then **tfind**() returns NULL.

tdelete() deletes an item from the tree. Its arguments are the same as for **tsearch**().

twalk() performs depth-first, left-to-right traversal of a binary tree. *root* points to the starting node for the traversal. If that node is not the root, then only part of the tree will be visited. **twalk**() calls the user function *action* each time a node is visited (that is, three times for an internal node, and once for a leaf). *action*, in turn, takes three arguments. The first argument is a pointer to the node being visited. The structure of the node is unspecified, but it is possible to cast the pointer to a pointer-to-pointer-to-element in order to access the element stored within the node. The application must not modify the structure pointed to by this argument. The second argument is an integer which takes one of the values **preorder**, **postorder**, or **endorder** depending on whether this is the first, second, or third visit to the internal node, or the value **leaf** if this is the single visit to a leaf node. (These symbols are defined in *<search.h>*.) The third argument is the depth of the node; the root node has depth zero.

(More commonly, **preorder**, **postorder**, and **endorder** are known as **preorder**, **inorder**, and **postorder**: before visiting the children, after the first and before the second, and after visiting the children. Thus, the choice of name **postorder** is rather confusing.)

twalk_r() is similar to **twalk**(), but instead of the *depth* argument, the *closure* argument pointer is passed to each invocation of the action callback, unchanged. This pointer can be used to pass information to and from the callback function in a thread-safe fashion, without resorting to global variables.

tdestroy() removes the whole tree pointed to by *root*, freeing all resources allocated by the **tsearch**()

function. For the data in each tree node the function *free_node* is called. The pointer to the data is passed as the argument to the function. If no such work is necessary, *free_node* must point to a function doing nothing.

RETURN VALUE

tsearch() returns a pointer to a matching node in the tree, or to the newly added node, or NULL if there was insufficient memory to add the item. **tfind**() returns a pointer to the node, or NULL if no match is found. If there are multiple items that match the key, the item whose node is returned is unspecified.

tdelete() returns a pointer to the parent of the node deleted, or NULL if the item was not found. If the deleted node was the root node, **tdelete**() returns a dangling pointer that must not be accessed.

tsearch(), **tfind**(), and **tdelete**() also return NULL if *rootp* was NULL on entry.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tsearch(), **tfind**(), **tdelete**()	Thread safety	MT-Safe race:rootp
twalk()	Thread safety	MT-Safe race:root
twalk_r()	Thread safety	MT-Safe race:root
tdestroy()	Thread safety	MT-Safe

STANDARDS

tsearch()
tfind()
tdelete()
twalk() POSIX.1-2008.

tdestroy()
twalk_r()
GNU.

HISTORY

tsearch()
tfind()
tdelete()
twalk() POSIX.1-2001, POSIX.1-2008, SVr4.

twalk_r()
glibc 2.30.

NOTES

twalk() takes a pointer to the root, while the other functions take a pointer to a variable which points to the root.

tdelete() frees the memory required for the node in the tree. The user is responsible for freeing the memory for the corresponding data.

The example program depends on the fact that **twalk**() makes no further reference to a node after calling the user function with argument "endorder" or "leaf". This works with the GNU library implementation, but is not in the System V documentation.

EXAMPLES

The following program inserts twelve random numbers into a binary tree, where duplicate numbers are collapsed, then prints the numbers in order.

```
#define _GNU_SOURCE     /* Expose declaration of tdestroy() */
#include <search.h>
#include <stddef.h>
#include <stdio.h>
#include <stdlib.h>
#include <time.h>

static void *root = NULL;

static void *
```

```
xmalloc(size_t n)
{
    void *p;

    p = malloc(n);
    if (p)
        return p;
    fprintf(stderr, "insufficient memory\n");
    exit(EXIT_FAILURE);
}

static int
compare(const void *pa, const void *pb)
{
    if (*(int *) pa < *(int *) pb)
        return -1;
    if (*(int *) pa > *(int *) pb)
        return 1;
    return 0;
}

static void
action(const void *nodep, VISIT which, int depth)
{
    int *datap;

    switch (which) {
    case preorder:
        break;
    case postorder:
        datap = *(int **) nodep;
        printf("%6d\n", *datap);
        break;
    case endorder:
        break;
    case leaf:
        datap = *(int **) nodep;
        printf("%6d\n", *datap);
        break;
    }
}

int
main(void)
{
    int  *ptr;
    int  **val;

    srand(time(NULL));
    for (unsigned int i = 0; i < 12; i++) {
        ptr = xmalloc(sizeof(*ptr));
        *ptr = rand() & 0xff;
        val = tsearch(ptr, &root, compare);
        if (val == NULL)
            exit(EXIT_FAILURE);
        if (*val != ptr)
            free(ptr);
    }
    twalk(root, action);
```

```
        tdestroy(root, free);
        exit(EXIT_SUCCESS);
    }
```

NAME

ttyname, ttyname_r − return name of a terminal

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <unistd.h>

char *ttyname(int fd);
int ttyname_r(int fd, char buf[.buflen], size_t buflen);
```

DESCRIPTION

The function **ttyname**() returns a pointer to the null-terminated pathname of the terminal device that is open on the file descriptor *fd*, or NULL on error (for example, if *fd* is not connected to a terminal). The return value may point to static data, possibly overwritten by the next call. The function **ttyname_r**() stores this pathname in the buffer *buf* of length *buflen*.

RETURN VALUE

The function **ttyname**() returns a pointer to a pathname on success. On error, NULL is returned, and *errno* is set to indicate the error. The function **ttyname_r**() returns 0 on success, and an error number upon error.

ERRORS

EBADF
: Bad file descriptor.

ENODEV
: *fd* refers to a slave pseudoterminal device but the corresponding pathname could not be found (see NOTES).

ENOTTY
: *fd* does not refer to a terminal device.

ERANGE
: (**ttyname_r**()) *buflen* was too small to allow storing the pathname.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ttyname()	Thread safety	MT-Unsafe race:ttyname
ttyname_r()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, 4.2BSD.

NOTES

A process that keeps a file descriptor that refers to a *pts*(4) device open when switching to another mount namespace that uses a different */dev/ptmx* instance may still accidentally find that a device path of the same name for that file descriptor exists. However, this device path refers to a different device and thus can't be used to access the device that the file descriptor refers to. Calling **ttyname**() or **ttyname_r**() on the file descriptor in the new mount namespace will cause these functions to return NULL and set *errno* to **ENODEV**.

NAME

ttyslot − find the slot of the current user's terminal in some file

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h> /* See NOTES */

int ttyslot(void);

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ttyslot():
Since glibc 2.24:
_DEFAULT_SOURCE
From glibc 2.20 to glibc 2.23:
_DEFAULT_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)
glibc 2.19 and earlier:
_BSD_SOURCE || (_XOPEN_SOURCE && _XOPEN_SOURCE < 500)

DESCRIPTION

The legacy function **ttyslot**() returns the index of the current user's entry in some file.

Now "What file?" you ask. Well, let's first look at some history.

Ancient history

There used to be a file */etc/ttys* in UNIX V6, that was read by the *init*(1) program to find out what to do with each terminal line. Each line consisted of three characters. The first character was either '0' or '1', where '0' meant "ignore". The second character denoted the terminal: '8' stood for "/dev/tty8". The third character was an argument to *getty*(8) indicating the sequence of line speeds to try ('−' was: start trying 110 baud). Thus a typical line was "18−". A hang on some line was solved by changing the '1' to a '0', signaling init, changing back again, and signaling init again.

In UNIX V7 the format was changed: here the second character was the argument to *getty*(8) indicating the sequence of line speeds to try ('0' was: cycle through 300-1200-150-110 baud; '4' was for the on-line console DECwriter) while the rest of the line contained the name of the tty. Thus a typical line was "14console".

Later systems have more elaborate syntax. System V-like systems have */etc/inittab* instead.

Ancient history (2)

On the other hand, there is the file */etc/utmp* listing the people currently logged in. It is maintained by *login*(1)It has a fixed size, and the appropriate index in the file was determined by *login*(1) using the **ttyslot**() call to find the number of the line in */etc/ttys* (counting from 1).

The semantics of ttyslot

Thus, the function **ttyslot**() returns the index of the controlling terminal of the calling process in the file */etc/ttys*, and that is (usually) the same as the index of the entry for the current user in the file */etc/utmp*. BSD still has the */etc/ttys* file, but System V-like systems do not, and hence cannot refer to it. Thus, on such systems the documentation says that **ttyslot**() returns the current user's index in the user accounting data base.

RETURN VALUE

If successful, this function returns the slot number. On error (e.g., if none of the file descriptors 0, 1, or 2 is associated with a terminal that occurs in this data base) it returns 0 on UNIX V6 and V7 and BSD-like systems, but −1 on System V-like systems.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ttyslot()	Thread safety	MT-Unsafe

VERSIONS

The utmp file is found in various places on various systems, such as */etc/utmp*, */var/adm/utmp*, */var/run/utmp*.

STANDARDS

None.

HISTORY

SUSv1; marked as LEGACY in SUSv2; removed in POSIX.1-2001. SUSv2 requires −1 on error.

The glibc2 implementation of this function reads the file **_PATH_TTYS**, defined in <*ttyent.h*> as "/etc/ttys". It returns 0 on error. Since Linux systems do not usually have "/etc/ttys", it will always return 0.

On BSD-like systems and Linux, the declaration of **ttyslot**() is provided by <*unistd.h*>. On System V-like systems, the declaration is provided by <*stdlib.h*>. Since glibc 2.24, <*stdlib.h*> also provides the declaration with the following feature test macro definitions:

```
(_XOPEN_SOURCE >= 500 ||
        (_XOPEN_SOURCE && _XOPEN_SOURCE_EXTENDED))
    && ! (_POSIX_C_SOURCE >= 200112L || _XOPEN_SOURCE >= 600)
```

Minix also has *fttyslot*(*fd*).

NAME

tzset, tzname, timezone, daylight − initialize time conversion information

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

```
#include <time.h>

void tzset(void);

extern char *tzname[2];
extern long timezone;
extern int daylight;
```

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

tzset():
_POSIX_C_SOURCE

tzname:
_POSIX_C_SOURCE

timezone, *daylight*:
_XOPEN_SOURCE
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _SVID_SOURCE

DESCRIPTION

The **tzset**() function initializes the *tzname* variable from the **TZ** environment variable. This function is automatically called by the other time conversion functions that depend on the timezone. In a System-V-like environment, it will also set the variables *timezone* (seconds West of UTC) and *daylight* (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present, or future when daylight saving time applies).

If the **TZ** variable does not appear in the environment, the system timezone is used. The system timezone is configured by copying, or linking, a file in the *tzfile*(5) format to */etc/localtime*. A timezone database of these files may be located in the system timezone directory (see the **FILES** section below).

If the **TZ** variable does appear in the environment, but its value is empty, or its value cannot be interpreted using any of the formats specified below, then Coordinated Universal Time (UTC) is used.

The value of **TZ** can be one of two formats. The first format is a string of characters that directly represent the timezone to be used:

```
std offset[dst[offset][,start[/time],end[/time]]]
```

There are no spaces in the specification. The *std* string specifies an abbreviation for the timezone and must be three or more alphabetic characters. When enclosed between the less-than (<) and greater-than (>) signs, the character set is expanded to include the plus (+) sign, the minus (−) sign, and digits. The *offset* string immediately follows *std* and specifies the time value to be added to the local time to get Coordinated Universal Time (UTC). The *offset* is positive if the local timezone is west of the Prime Meridian and negative if it is east. The hour must be between 0 and 24, and the minutes and seconds 00 and 59:

```
[+|-]hh[:mm[:ss]]
```

The *dst* string and *offset* specify the name and offset for the corresponding daylight saving timezone. If the offset is omitted, it defaults to one hour ahead of standard time.

The *start* field specifies when daylight saving time goes into effect and the *end* field specifies when the change is made back to standard time. These fields may have the following formats:

Jn This specifies the Julian day with *n* between 1 and 365. Leap days are not counted. In this format, February 29 can't be represented; February 28 is day 59, and March 1 is always day 60.

n This specifies the zero-based Julian day with *n* between 0 and 365. February 29 is counted in leap years.

M*m.w.d*
: This specifies day *d* (0 <= *d* <= 6) of week *w* (1 <= *w* <= 5) of month *m* (1 <= *m* <= 12). Week 1 is the first week in which day *d* occurs and week 5 is the last week in which day *d* occurs. Day 0 is a Sunday.

The *time* fields specify when, in the local time currently in effect, the change to the other time occurs. If omitted, the default is 02:00:00.

Here is an example for New Zealand, where the standard time (NZST) is 12 hours ahead of UTC, and daylight saving time (NZDT), 13 hours ahead of UTC, runs from the first Sunday in October to the third Sunday in March, and the changeovers happen at the default time of 02:00:00:

```
TZ="NZST-12:00:00NZDT-13:00:00,M10.1.0,M3.3.0"
```

The second format specifies that the timezone information should be read from a file:

```
:[filespec]
```

If the file specification *filespec* is omitted, or its value cannot be interpreted, then Coordinated Universal Time (UTC) is used. If *filespec* is given, it specifies another *tzfile*(5)-format file to read the timezone information from. If *filespec* does not begin with a '/', the file specification is relative to the system timezone directory. If the colon is omitted each of the above **TZ** formats will be tried.

Here's an example, once more for New Zealand:

```
TZ=":Pacific/Auckland"
```

ENVIRONMENT

TZ If this variable is set its value takes precedence over the system configured timezone.

TZDIR
: If this variable is set its value takes precedence over the system configured timezone database directory path.

FILES

/etc/localtime
: The system timezone file.

/usr/share/zoneinfo/
: The system timezone database directory.

/usr/share/zoneinfo/posixrules
: When a TZ string includes a dst timezone without anything following it, then this file is used for the start/end rules. It is in the *tzfile*(5) format. By default, the zoneinfo Makefile hard links it to the *America/New_York* tzfile.

Above are the current standard file locations, but they are configurable when glibc is compiled.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
tzset()	Thread safety	MT-Safe env locale

STANDARDS

POSIX.1-2008.

HISTORY

POSIX.1-2001, SVr4, 4.3BSD.

4.3BSD had a function **char *timezone(***zone***,** *dst***)** that returned the name of the timezone corresponding to its first argument (minutes West of UTC). If the second argument was 0, the standard name was used, otherwise the daylight saving time version.

NAME

ualarm − schedule signal after given number of microseconds

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <unistd.h>

useconds_t ualarm(useconds_t *usecs***, useconds_t** *interval***);**

Feature Test Macro Requirements for glibc (see *feature_test_macros*(7)):

ualarm():
Since glibc 2.12:
(_XOPEN_SOURCE >= 500) && ! (_POSIX_C_SOURCE >= 200809L)
|| /* glibc >= 2.19: */ _DEFAULT_SOURCE
|| /* glibc <= 2.19: */ _BSD_SOURCE
Before glibc 2.12:
_BSD_SOURCE || _XOPEN_SOURCE >= 500

DESCRIPTION

The **ualarm**() function causes the signal **SIGALRM** to be sent to the invoking process after (not less than) *usecs* microseconds. The delay may be lengthened slightly by any system activity or by the time spent processing the call or by the granularity of system timers.

Unless caught or ignored, the **SIGALRM** signal will terminate the process.

If the *interval* argument is nonzero, further **SIGALRM** signals will be sent every *interval* microseconds after the first.

RETURN VALUE

This function returns the number of microseconds remaining for any alarm that was previously set, or 0 if no alarm was pending.

ERRORS

EINTR
Interrupted by a signal; see *signal*(7).

EINVAL
usecs or *interval* is not smaller than 1000000. (On systems where that is considered an error.)

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ualarm()	Thread safety	MT-Safe

STANDARDS

None.

HISTORY

4.3BSD, POSIX.1-2001. POSIX.1-2001 marks it as obsolete. Removed in POSIX.1-2008.

4.3BSD, SUSv2, and POSIX do not define any errors.

POSIX.1-2001 does not specify what happens if the *usecs* argument is 0. On Linux (and probably most other systems), the effect is to cancel any pending alarm.

The type *useconds_t* is an unsigned integer type capable of holding integers in the range [0,1000000]. On the original BSD implementation, and in glibc before glibc 2.1, the arguments to **ualarm**() were instead typed as *unsigned int*. Programs will be more portable if they never mention *useconds_t* explicitly.

The interaction of this function with other timer functions such as *alarm*(2), *sleep*(3), *nanosleep*(2), *setitimer*(2), *timer_create*(2), *timer_delete*(2), *timer_getoverrun*(2), *timer_gettime*(2), *timer_settime*(2), *usleep*(3) is unspecified.

This function is obsolete. Use *setitimer*(2) or POSIX interval timers (**timer_create**(2), etc.) instead.

SEE ALSO

alarm(2), *getitimer*(2), *nanosleep*(2), *select*(2), *setitimer*(2), *usleep*(3), *time*(7)

NAME

ulimit − get and set user limits

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <ulimit.h>

[[deprecated]] long ulimit(int *cmd***, long** *newlimit***);**

DESCRIPTION

Warning: this routine is obsolete. Use *getrlimit*(2), *setrlimit*(2), and *sysconf*(3) instead. For the shell command **ulimit**, see *bash*(1)

The **ulimit**() call will get or set some limit for the calling process. The *cmd* argument can have one of the following values.

UL_GETFSIZE
: Return the limit on the size of a file, in units of 512 bytes.

UL_SETFSIZE
: Set the limit on the size of a file.

3 (Not implemented for Linux.) Return the maximum possible address of the data segment.

4 (Implemented but no symbolic constant provided.) Return the maximum number of files that the calling process can open.

RETURN VALUE

On success, **ulimit**() returns a nonnegative value. On error, −1 is returned, and *errno* is set to indicate the error.

ERRORS

EPERM
: An unprivileged process tried to increase a limit.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ulimit()	Thread safety	MT-Safe

STANDARDS

POSIX.1-2008.

NAME

undocumented − undocumented library functions

SYNOPSIS

Undocumented library functions

DESCRIPTION

This man page mentions those library functions which are implemented in the standard libraries but not yet documented in man pages.

Solicitation

If you have information about these functions, please look in the source code, write a man page (using a style similar to that of the other Linux section 3 man pages), and send it to **mtk.man-pages@gmail.com** for inclusion in the next man page release.

The list

authdes_create(3), *authdes_getucred*(3), *authdes_pk_create*(3), *clntunix_create*(3), *creat64*(3), *dn_skipname*(3), *fcrypt*(3), *fp_nquery*(3), *fp_query*(3), *fp_resstat*(3), *freading*(3), *freopen64*(3), *fseeko64*(3), *ftello64*(3), *ftw64*(3), *fwscanf*(3), *get_avphys_pages*(3), *getdirentries64*(3), *getmsg*(3), *getnetname*(3), *get_phys_pages*(3), *getpublickey*(3), *getsecretkey*(3), *h_errlist*(3), *host2netname*(3), *hostalias*(3), *inet_nsap_addr*(3), *inet_nsap_ntoa*(3), *init_des*(3), *libc_nls_init*(3), *mstats*(3), *netname2host*(3), *netname2user*(3), *nlist*(3), *obstack_free*(3), *parse_printf_format*(3), *p_cdname*(3), *p_cdnname*(3), *p_class*(3), *p_fqname*(3), *p_option*(3), *p_query*(3), *printf_size*(3), *printf_size_info*(3), *p_rr*(3), *p_time*(3), *p_type*(3), *putlong*(3), *putshort*(3), *re_compile_fastmap*(3), *re_compile_pattern*(3), *register_printf_function*(3), *re_match*(3), *re_match_2*(3), *re_rx_search*(3), *re_search*(3), *re_search_2*(3), *re_set_registers*(3), *re_set_syntax*(3), *res_send_setqhook*(3), *res_send_setrhook*(3), *ruserpass*(3), *setfileno*(3), *sethostfile*(3), *svc_exit*(3), *svcudp_enablecache*(3), *tell*(3), *thrd_create*(3), *thrd_current*(3), *thrd_equal*(3), *thrd_sleep*(3), *thrd_yield*(3), *tr_break*(3), *tzsetwall*(3), *ufc_dofinalperm*(3), *ufc_doit*(3), *user2netname*(3), *wcschrnul*(3), *wcsftime*(3), *wscanf*(3), *xdr_authdes_cred*(3), *xdr_authdes_verf*(3), *xdr_cryptkeyarg*(3), *xdr_cryptkeyres*(3), *xdr_datum*(3), *xdr_des_block*(3), *xdr_domainname*(3), *xdr_getcredres*(3), *xdr_keybuf*(3), *xdr_keystatus*(3), *xdr_mapname*(3), *xdr_netnamestr*(3), *xdr_netobj*(3), *xdr_passwd*(3), *xdr_peername*(3), *xdr_rmtcall_args*(3), *xdr_rmtcallres*(3), *xdr_unixcred*(3), *xdr_yp_buf*(3), *xdr_yp_inaddr*(3), *xdr_ypbind_binding*(3), *xdr_ypbind_resp*(3), *xdr_ypbind_resptype*(3), *xdr_ypbind_setdom*(3), *xdr_ypdelete_args*(3), *xdr_ypmaplist*(3), *xdr_ypmaplist_str*(3), *xdr_yppasswd*(3), *xdr_ypreq_key*(3), *xdr_ypreq_nokey*(3), *xdr_ypresp_all*(3), *xdr_ypresp_all_seq*(3), *xdr_ypresp_key_val*(3), *xdr_ypresp_maplist*(3), *xdr_ypresp_master*(3), *xdr_ypresp_order*(3), *xdr_ypresp_val*(3), *xdr_ypstat*(3), *xdr_ypupdate_args*(3), *yp_all*(3), *yp_bind*(3), *yperr_string*(3), *yp_first*(3), *yp_get_default_domain*(3), *yp_maplist*(3), *yp_master*(3), *yp_match*(3), *yp_next*(3), *yp_order*(3), *ypprot_err*(3), *yp_unbind*(3), *yp_update*(3)

NAME

ungetwc − push back a wide character onto a FILE stream

LIBRARY

Standard C library (*libc*, *−lc*)

SYNOPSIS

#include <wchar.h>

wint_t ungetwc(wint_t *wc***, FILE ***stream***);**

DESCRIPTION

The **ungetwc**() function is the wide-character equivalent of the *ungetc*(3) function. It pushes back a wide character onto *stream* and returns it.

If *wc* is **WEOF**, it returns **WEOF**. If *wc* is an invalid wide character, it sets *errno* to **EILSEQ** and returns **WEOF**.

If *wc* is a valid wide character, it is pushed back onto the stream and thus becomes available for future wide-character read operations. The file-position indicator is decremented by one or more. The end-of-file indicator is cleared. The backing storage of the file is not affected.

Note: *wc* need not be the last wide-character read from the stream; it can be any other valid wide character.

If the implementation supports multiple push-back operations in a row, the pushed-back wide characters will be read in reverse order; however, only one level of push-back is guaranteed.

RETURN VALUE

The **ungetwc**() function returns *wc* when successful, or **WEOF** upon failure.

ATTRIBUTES

For an explanation of the terms used in this section, see *attributes*(7).

Interface	Attribute	Value
ungetwc()	Thread safety	MT-Safe

STANDARDS

C11, POSIX.1-2008.

HISTORY

POSIX.1-2001, C99.

NOTES

The behavior of **ungetwc**() depends on the **LC_CTYPE** category of the current locale.
